The power supply hum is audible on AM on on CW, it probably affects SSB too, as intermodulation, but the steep bass cut off of the IF filters makes it hard to hear.
The small added cap I put in the ring modulator is still working. I used a dipped silvered mica. I think its 10 pf. Anyway I get a perfect carrier null, I mean there just

isn't any carrier.
SSB quality is pinched as others have stated. I think this is just the narrowness of the filters and the distance they are from the effective carrier position. Good intelegibility but not quite natural sounding. On AM, where everything is shifted to the lower sideband filter there is reasonable bass so I think this is not the fault of the audio amplifier circuits. Also, I centered the carrier carefully between the filters and both upper and lower sideband sound alike. I made the listening test using an SP-600-JX because it has an 8 khz wide IF filter so it does not cut anything that the TX is sending. Same for AM. I used a microphone driven by a small speaker to provide the test signal. Of course, this was all done using a dummy load. There is enough leakage from the T connector I use to connect the scope across the RF to provide a signal across the room.
Tomorrow I will finish tuning and see how much difference that makes on the power on other bands. At some point I also should remove the front panel and clean the stuff under it. I will try to find a suitable bit of blue plastic foil for the meter and dial. I held off doing this before because I was so frustrated by the carrier null problem and did not want to put too much work in a unit that might turn out to be non-functioning.
This has been very wordy. I am sending it along in case it might be helpful to others and also, to be frank, because I don't know anyone outside of the mailing lists I belong to that has any slightest interest in the stuff than fascinates me. Maybe that's why were are all here.
Needless to say any suggestions, criticisims, warnings, contratulations, etc, etc, would be welcome. Thank you all for putting up with me and to Gary especially for his expertise and genuine interest.

I misread his letter. He has PCBs on back order and
expects them in a few days. I am adding this in case anyone
was discouraged from ordering the kit by thinking there
would be a long delay. My fault, its not the case.

The R4-B has it's own built-in power supply. It can be used as a receiver without the matching transmitter.

Oh, dear, another thing I forgot. If you do not have the

manuals I recommend you get the CD from Gary Burrell which

has both RX and TX manuals and a lot of other stuff on it.

There _are_ some decent downloadable manuals on the web but

the ones at BAMA are very low resolution and not too useful.

Gary's web site is:

3089. TR7 Power Supply

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-01-17 12:15:29 UTC
From: Adrian Rees
Topic: 3066 Message: 3089

Hello everyone

First of all Happy New Year !

Secondly I am re-building my TR7, and at the moment I am working on the power control board. (the one with the 10K & 1K trimmers on it. So far I've replaced the normal single turn trimmers with 10 turn ones, and replaced the TIP31's (one was damaged, so I thought replace both).

The small transformer on this board is damaged. The core has split either side of the coil. So I guess superglue or epoxy the the core together ?

Cheers

Adrian MW1LCR

Adrian -

Common problem. The core is actually two "E" shaped pieces that
"super-glue" (cyanoacrylate) together. Drake musta' used cheap glue, as
it only held for about 40 years.... :-)

The Sencore is advertised as a "Waveform Analizer" It does have most of the gimmicks u mentioned, dual trace, invert, T Delta measurement (?????) & also includes a digital volt meter & freq. counter. For $88 on ebay I'm trying to remain positive abt it's condition.....money back gaurantee !

I'm looking forward to some basic suggestions on using it from u and anyone else who might like to contribute.

Delta T is a method of measuring period. The usual arrangement is to have a pair of movable markers on the screen, the time delay between them is displayed on a readout or, in more recent scopes, on the screen. One can measure the period of a waveform using the markers. Most of these will also invert period and readout in frequency. The frequency counter part of the instrument is probably connected to this.
To me a waveform analyser is a different instrument, a tunable voltmeter with calibrated frequency and voltage, essentially a simplified spectrum analyser. Spectrum analysers make swept measurements and display them as a graph of frequency vs: voltage. A wave analyser of the sort I am talking about will make much the same measurement but usually does not have a CRT readout or built-in sweep. Spectrum analysers are extrememly useful for RF work and much audio work. Unfortunately, the antiques I worked on at Hewlett-Packard what seems a lifetime ago are still considered desirable and are too rich for my blood.

Sure

Fixed with epoxy & a tiny cable tie.

Just setting up the voltages and going to have a look at the DR7 as its all over the place.

Thanks

3094. Mics for Drakes

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-01-18 15:04:27 UTC
From: Henry
Topic: 3094 Message: 3094

I have finally got a Drake station in operation! The question I have is what is the best mic to use with my station and has anyone used the Heil mic that is designed for Drake radios? I currently have a Shure 444 on it and get mixed audio reports some say it sounds great and others say it sounds like I am talking through a tube. I have used Heil mics with all my other rigs and had great results. Also has anyone ever used the W2HIY equipment with Drakes? As I stated new to the Drake set up and want to make mine as good as it can be! Thanks in advance for your help!

3095. RE: [DrakeRadio] Mics for Drakes

Henry,

I use a 444D (set on high impedance) with my TR7A and a EV 719 or 664 mic with my B-line and get excellent reports. I also have a Heil Goldline Vintage mic w/W2IHY 8 Band EQ which I use with the B-line and it works well also. Remember that the EQ will help you tailor your voice characteristics more between the mic and radio but you're still limited by the filter bandwidth of the radio.

Thanks Jim. I am running a R-4B with T-4XC transmitter. I also have an L-4B that I have not hooked up to the Drakes yet. I aseriously considering the W2IHY system just so I can make it sound like I do and I like Heil mics so more than likely going to use that mic I just did not want to do that without hearing from someone who has done it. One other question are there any aftermarket filters to install that will improve the Drakes?

Henry,

Because the T4XC filter is about 2.4khz, you'll be limited in transmit bandwidth. It still will sound decent with the 8 band EQ but if you're looking for ESSB quality audio, that won't happen. If I was to do it all over, I would get the W2IHY EQ Plus as it offers more than enough EQ (3 bands) but also has compressor as well.

Henry,

I've tried all the current display offerings and find that the ESP (Electronic Specialty Products) unit to be the best for my station. I have one for the B-Line and one for my Galaxy GT-550A.

Thanks for you wisdom Jim. I was looking at the EQPlus and I am fairly sure I will get that at Hamcation in Orlando next month. I also want a digital read out for my Drake station. Any idea where I can get the plugs to interface the amp?

If I was to do it all over, I would get the W2IHY EQ Plus as it offers more than enough EQ (3 bands) but also has compressor as well.

I aseriously considering the W2IHY system just so I can make it sound like I do and I like Heil mics so more than likely going to use that mic I just did not want to do that without hearing from someone who has done it. One other question are there any aftermarket filters to install that will improve the Drakes?

Topic: 3100 Message: 3100

I am the proud new owner of a mint Drake L-7 and want to ask a question concerning the EIMAC 3-500Z tubes that are in it. The tubes were removed before shipment of the amp and are in a small box wrapped in bubble wrap. When I put the tubes back in should I have any concern about getting my finger prints (skin oil) on the glass of the tube.

I know with halogen bulbs this can shorten the life, so is there any special care to be taken when cleaning the glass off before insertion and reassembly.

I waited years and years for an amp and in my opinion now own the best there is, so I want to make sure I take care of her as much as possible.

Bob,

The first thing I would do is buy an upgrade Cap board (unless it already has one installed) for the PS.

Hi Jim

The power supply has all the upgrades, I checked first thing after inspecting the FedEx monkeys work which bent the front flat panel of the ps. The internals are all good to go, but they bent the right top corner by placing something heavy on top of it.

I have another ham who owns a fab shop who has offered once I settle with FedEx to let me ship the front panel and he will make me a total new one, just like the old one.

Bob

Congrats on the L7, I purchased mine new in 1979 and still have it. You can touch the tubes no problem. Now, how long have the tubes been in storage?If the answer is several months, I would turn the amp on and let in idle for a few hours before applying RF of course with the tubes in their sockets and filament lit.. Eimac use to say 20 hours before applying RF. The 3-500 can get gassy while in storage and this method is suppose to burn off the gas. There are those who will not agree with this but just my two cents worth.

Thank you

It has not been in storage, they were used by another ham over the last 4 years from time to time, but not often. They are the Eimac version of tube and seem to be in really good shape. He said he could get out 1400W on 10 meters, so that is a good sign I have been told.

The only question I have right now is how do you tell if the amp itself has the softkey or softstart mod done to it. Where do you look for the softkey especially.

I have noticed a small board with 1/8 watt resistors and a few diodes which connects directly to the (XMITR OUPUT AGC LINE) phono plug on the back, not sure if this is a softkey mod or not.

Also how do you tell if it has the fast switching relay in it. I have found the mods online, but it doesn't tell you how to tell if you need them or not.

From: jimburlile
Topic: 3100 Message: 3106

Hi Bob;

Congratsulations on getting the L7, I have my eye on one that a member of the club I am in has and is not using.

I have a little experiance with big tubes, but my father was a first class teleg guy who took care of transmitters for several stations in Ohio years ago.

I used to go with him at times when I was young and do the crawling in and out of the transmitters when doing replacements and mods ect..

For what it is worth the old guys who were in charge of these transmitters, would with out fail allways wipe the tubes down with alcohol and dry them then handle them with white cotton gloves to ensure no fingerprints were on the glass.

I have an idea that in a ham linear it is probbily not nearly as important as a TX running 10K watts 24 hrs a day, but if it were mine I would not leave fingerprints on them.

Jim.

From: Jim Shorney
Topic: 3094 Message: 3107

Any decent high impedance mic should sound good. The 444 has a mellow, natural sound that works well for casual rag chewing. A ceramic mic, such as the D-104 (modded with an added 470K resistor), EV 729, Turner 254HC, etc., are good DXing and contesting mics.

From: Kris Merschrod
Topic: 3094 Message: 3108

Jim is right on the mark - keep the audio system simple, use what was designed for the Drake, and focus on speaking clearly!

I also liked Garey's " What for?" today on the dummy-loaded TR-4 with SB101.

Keeping things simple is one way to enjoy the hobby; I guess that driving a square peg in a round hole is also enjoyable too :>)

My sources say that you need color in the plates to getter the tubes. I'll run the amp in CW mode key-down with no drive for a few minutes with some red glow in the plates, then let things cool for a while. Rinse and repeat.

I think I just answered this on another list. :)

You need the manual, your eyes, and what is between your ears. Look for something that isn't there in the pictures, and isn't on the schematic. A soft key will be connected between the T/R relay coil and the VOX jack on the back. A soft-start will be wired into the 110/220 primary circuit. The location and appearance of each will vary depending on the mod and the modder.

Be careful. This amp is quite capable of killing you. If you don't understand any of the above, or aren't familiar with high voltage safety protocols, I strongly suggest that you take the amp to someone who is comfortable with servicing this type of equipment.

Hi Jim

Thanks for the information. I looked inside and the only board I have is a small one which connects to the 'XMITR AGC OUTPUT' phono plug.

I didn't see that in this very poor pdf attempt at a manual, but it isn't going to the VOX phono for sure. I also don't see anything at the changeover relay.

So guess I have some work to do. I would like to have both since I enjoy very much cw.

Also, I will be very careful, never worked on one of these but used to repair tv sets in the old days. So will be cautious.

From: VE3FMC
Topic: 3112 Message: 3112

Can anyone tell me if there is the normal blue filter in behind the RV-4 tuning dial?
Thanks

OK I tore em apart and pulled the old blue filters out. Now with the new blue LED bulbs installed the TR-4C/RV-4 look really good in the dark!

From: VE3FMC
Topic: 3114 Message: 3114

I recently replaced the original bulbs in my TR-4C/RV-4 with blue led bulbs I purchased from Don N9OO.

I removed the original blue plastic filters behind the tuning dials and the S meter before installing the new bulbs.

Now there is a nice soft blue glow behind the S meter and tuning dials.
Looks great.

Here is Don's website
http://www.radiolabworks.com/products/4linelamps/4linelamp.html

I just finished replacing the blue gels in the T-4XB I
am slowly repairing. Considering the difficulty of finding
suitable material and the work involved in replacing it the
above looks like a good deal. I finally found what I wanted
in a large local art supply store after looking at a few
others. It took two layers to get the color right. My R-4B
which looked alright before now looks a bit greenish in
comparison. Since the guy has to make these lamps by hand
and considering their long life the price seems quite
reasonable.

I tried to find something specific in the Eimac books I
have available but couldn't. My memory is that the envelopes
of these tubes should be very clean to prevent strains from
localized heating since the tubes run _very_ hot in use.
This was also true of the old Eimac triodes. The tubes use
plate material containing tantalum which acts as a getter
when at red heat. The tubes are designed to run with the
plates at red to yellow heat. I would clean the tubes with
diswashing detergent and make sure there is no residue and
then handle them with gloves. Food handling gloves will do.
I am quite sure there is something in Eimac or Varian
literature about this.
I am not so sure about electron bombardment heating of
residue on the bulb but that may also be a concern, the
localized heating I am writing about is from simple
absorption by a substance on the surface.

Thanks for the link. This looks like the ideal answer. I
think LEDs will run on AC as well as DC. I tried this with a
makeshift and it seems to work.

Richard,

This site was brought up on the Drake Net last Spring and since then, I've bought a !@#! load of LED's from them. Great stuff and priced right.

Hi Richard,
I have the BA9s-B which is a 6V AC/DC and I see I also have a BA9s-W in 12 V AC/DC. I used these in my 4 line and 7 line- I don't recall which was which now.

The TR-7 and accessories use 12V DC for the lamps (really, about 13.4 if you want to get picky). IIRC, the L-7 runs the lamps off the tube filament supply, which would be 5V AC.

Both the R-4C and the T-4CX use the #47 bulb, it's on the schematic and should be listed on the parts list too. It's a 6.3 volt, .15 amp bulb.

3126. R-4C sensitivity on 20m

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-01-21 13:10:23 UTC
From: Steve
Topic: 3126 Message: 3126

Hi to all - I'm new to the group and to Drake, it's really good to see a forum where help can be found with these great old radios.

Anyway, my R4C is working well, except that recently the sensitivity on 20m seems to have dropped. Alongside other radios, it's about 2 S-points down, and the calibration signal gives an S8-9 only - and about S6-7 on intermediate frequencies between the higher readings.

On all other bands 80m - 10m the calibration signal gives well over S9.

When not connected to an aerial, I can only just detect an increase in background when tuning the preselector - on the other bands it is easy to hear.

Given that this problem is specific to 20m, does it look like an alignment issue? When I bought the radio 2 months ago, it was fine on all bands. If it is alignment, I wonder what could have caused a movement over a couple of months - I haven't had the box open except to take some pictures when I bought the rig.

Any help in this would be great, thanks and 73, Steve, MW0KST.

When everyone gets their new LED's, please let us know what you think about the diffusion (how even is the light over the dial), and how close is the color to the original blue with a slight tinge of green (Lee Lighting 172, "Lagoon Blue")?

I have tried several, and all are that horrible BLUE typically seen on stereos and VCRs, and has a bright, (often purple,) spot in the middle of the dial.

They've been the "right" color for 40+ years, just me I guess.....

Garey

Thanks for info - see what you mean about the voltages, series, parallel etc.

Yes, the schematic does say #47 but I haven't a clue what that means. If I walked into a store here and asked for a #47 bulb I would get blanked. All I was asking was what type No. on that catalogue is the equivalent to the #47.

Re the display, I have a couple of rigs here fitted with those hand made LED's and they do tend to look like modern sterios etc. but nevertheless quite attractive and no purple spot in the middle. I also have another two with normal #47 which have gone green. Both work as well as each other so I guess it's a matter of what pleases the eye rather than the ear.

Thanks again, Garey

The #47 is a standard small lamp used for pilot and
dial lamps. Even Radio Shack has them. Small bayonet base,
6.3 volts 150 ma.

At the time the T4 and R4 were made a sort of greenish
blue color seems to have been popular for dials and meters.
To my eye this was very close to the color of the newer
"burn-proof" phosphors used in CRTs and magic eye tubes of
the time. The older P-2 phosphor was definitely green, this
phosphor was nearly blue although of the same persistance,
etc, as the older phosphor.

If you like the "incandescent look" try replacing the #47 with a #755 indicator lamp. Same ratings, much longer life expectancy than a #47. Since I started using them in all the radios that call for the 47, I have never had to replace them!..

I did some searching and came up with this, AR88 Pilot bulbs lamps. I don't know if it cross references to what you use over there but it's the only thing I could find. It's suppose to be the same as a #47 bulb/lamp. Here is a link to a place that sells the #47 bulbs in the UK.
http://www.t2retail.co.uk/Bulbs/47_Bayonet_Base_lamp_Bulb

The #47 is a standard small lamp used for pilot and

dial lamps. Even Radio Shack has them. Small bayonet base,

6.3 volts 150 ma.

Richard,

Have you noticed how fast the modern #47 lamps burn out? Not like the ones we used back in the 50's or so. You can not find them with brass bases anymore either. Very seldom do I ever see those.

I have got blue LED's in my twins and one of the TR-4's. They seem to look nice to me, but not the same blue as with the clear #47 and blue/white plastic. Just my opinion. You can follow the link in my signature line at the bottom of the email and look at the twins.

In fact I notice this generally with incandescent bulbs. I added series resistors to the dial string in my SP-600 because the bulbs lasted only a couple of months. This may be partly due to high line voltage. The resistor extends the life considerably, maybe a year or more. I have not tried the 755 lamps yet but it seems a logical next step. I could also use #44 lamps. The additional current draw would lower the voltage even more. While a direct comparison shows the lamps are dimmer with the series resistor its not by much and I found them too bright to begin with.

Not really. A scan of a good dial printed on a transparent label and stuck on one of the clear CD pieces at the bottom and top of every stack of CDs might could be made to work. Otherwise one from a parts donor.

3142. PA1HFO PIN diode attenuator for the TR7

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-01-24 17:24:47 UTC
From: floydsense
Topic: 3142 Message: 3142

I have a new article on my website describing how I implemented Mark Stralen's PIN diode attenuator for the TR7. Mark's original article didn't explain how the bandswitch position was sensed and I worked out an approach to that. Here's the link:

http://www.k8ac.net/Attenuator.html

Email me if any questions.

From: de_n7ioh
Topic: 3145 Message: 3145

I have the following extra crystals that I do not need for sale or trade. I am asking $15 each plus shipping from, Payson, Arizona, 85541. I am in need of two 12.6 mHz crystals for the 160 meter band. One 29.1 mHz crystal and one 35.6 mHz crystal for the 17 and 12 meter bands.

For sale or trade:
One 25.1 mHz 20 meter band
One 32.1 mHz 15 meter band
Two 39.6 mHz 10 meter band, 28.5 - 29 mHz
One 38.1 mHz CB band, 27 - 27.5 mHz
One 38.6 mHz CB band, 27.5 - 28 mHz

Please contact me off the list.

Al, n7ioh

It may be a bit costly but you could screen print a copy of an original dial on to a new piece of plastic. Have heard of those restoring the copper frames using that process to replace the labels. The pic, of course, would have to be from directly overhead to avoid distortion and may need some scaling once you got it. But I
think it very possible.

Someone here may have one apart to make a good pic for you. Or, just maybe, Drake might happen to have a copy of that template...ok, probably not there but stranger things have happened.

God bless

It might be worthwile to contact a few Lexan suppliers and see how much it
would cost to stamp out a bunch of disks of the appropriate size.

Yep..I have been looking. They dont stamp that stuff to.. they are generally cast or molded and then machined perfect after that. Thin lexan sheet is pretty cheap and some time with a jig saw would get a dial. Lexan (Polycarbonate) is very soft however and it is really difficult to work with without scratching it.

While I haven't measured one yet, the CD dummy disks look to be nearly a perfect solution unless you needed alot of them.

Been looking for the suppliers of THOSE disks.

I'll keep everyone up to date on what I find.

Thanks to all.

"Back in the day", many years ago I was making test fixture safety covers out of Lexan. I was able to bend it, cut it, drill it, etc., very much like sheet metal. It also seemed very resistant to light scratches, more so than Plex, and didn't shatter like Plex. Seemed like magical stuff at the time.

Yes it is majic material for sure. Its compliant nature is what makes it so strong I think. We made offshore deck hatch covers from it and 1/4 inch of Lexan is immensely strong. You are correct about its formability too. works almost like hardwood. saw it, cut it,..you can use a router on it. Drills easy.

For a dial that was clear, if you left the protective paper on it, and were careful, it would be fine. But look at how the surface of a CD gets easily scratched if handled..that is lexan. Maybe not quantum worse than plexi, but it is softer so even a paper towel will put micro scratches in it it.

Its almost gummy or chewy compared to plexi which is quite brittle. Really notice it when drilling.

Good stuff...

Much too my surprise, one of the nicest Drake B series twins I have seen in many a year, was just given to me. (As well as the speaker and AC-3 power supply and all cables and original manuals!) It almost looks like it just came out of Joe's Ham Radio Sales, 35 years ago!

I say, 'almost' as the copper is no longer bright 'copper', rather, it has taken on a very golden patina of aged varnish! There isn't one speck of copper blight on either piece....just gorgeous! How was I so lucky?!!! Perhaps I will snap some images and put them in the photo section.......

OK, to my question....Hmmmmm...ya know...before I ask...think I will go peruse the files section...was going to ask how to add 17 meters....but...the info may already be posted so a question would be un-needed...

I have been told by the gurus that the original clear dial disks in C-line (and 7-line, by implication) are Lexan. It works fine in that application, and light surface scratches don't seem to be a problem. In fact, when I've had 7-line PTOs out, I didn't note a tendency to scratch easily at all. Not that I was trying to scratch them, mind you.... :) Maybe it's a different material after all. I did abuse one dial for quite a while trying to polish out a white chemical splotch with a Dremel and a buffing wheel. Finally got it out, did not note any signifigant scratching from handling afterwards.

I've got one TR-4 around here I got from someone with a dark brown section of dial too. I am sure it got that way setting for a long time in one spot and exposed to the sun. It is really dark brown. Good news is it is not my only Drake radio. I suspect the brown spot cannot be removed from the old dial.

The way I look at it, the only fix is to replace the dial from a donar radio, or spend big bucks and have a new dial made , or live with the problem. The only other option is to wait and see if anyone steps up to the plate and has them remanufactured. I know someone has a nice fix for Heathkit drum dials. They cut a tube to length and then applied a clear dial film with black lettering over the new plastic drum. This could be done for Drake flat dials too. It's just more then I want to deal with.

I never handled mine long enough to get a feel for whether it was Lexan or not.. I would be surprised if it were since I have never seen lexan turn broun from the Sun..Like I said, we used it for port windows and hatch cover lights on boats.

The good news is that like you said Jim, small scratches kind of disappear when the dial is seen in situ. Looking thru it against a white/blue background, they just don't show up. I always use a mild dish washing detergent and a soft dish cloth to wash and then just dab dry with another soft towel...no paper towels.

I'm sure there isn't enough of a market for these to tool up for all the different styles, but if I can assemble the samples for several, and find the project time, I will do the artwork and have the dry transfer photo internegative created--this will mean I could supply them, one at a time, but for a reasonable cost.

When I get started, I might ask to borrow a couple of dials if I don't have them..broken or brown ones wud be ok. But I have LAte ser style T-4, early and late TR-3, R and T 4 A and B. I will want the negative to include as many styles as I can get on a large sheet.

Curt

I have used lexan for tablesaw and router table parts. Great stuff there....but...I have never got it as warm as it will get in a radio. Could it warp while on edge with that heat, being that thin? I would think, initially, that something a bit harder may be better.

It was mentioned also that that may have been the original material. I wonder.

God bless

I think it would be fine temperature wise. They make DVDs and CDs out of it and they get pretty hot when being burned.

Check out AF4K's web site for Drake crystals. He packages modern crystals in used HC6/u holders. See the list of Drake compatible crystals here:
http://www.af4k.com/hc6u_crystals.htm

Look in your manual for the appropriate crystal for the 17M band. I bought crystals from Brian for 160, 30, 17, 12, and the bottom 500Khz of 10M. All work fine.

3166. Drake 1-A Receiver Alignment.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-01-28 16:12:35 UTC
From: w1fued@sbcglobal.net
Topic: 3166 Message: 3166

Hi Does anyone have experience with Drake 1-A receiver alignment?

I have tried to align it as per the book and worked well except for the aligment of the 2.9-3.5 overcoupling transformer.
Following the steps with a signal generator at 3.2 and dial 3.8, I am unable to see the peak and null of the t-1 transformer as described.
The transformer appears to be ok as adjusting it brings up one band edge, but then fouls up the other end. I know this adjustment is not so coarse as movement of the slugs changes the edges dramatically.

Does any one have any ideas or suggestions?
Help would be aprreciated.
Thanks,
Ed

From: David
Topic: 3170 Message: 3170

Hi,
Does anyone have an L-4B parts listing? I'm particular, I'm interested in findind a replacement for the ALC/Standby pot/switch. Mine appears to be audio taper and is kinda touchy toward the top end. I've compensated by turning back my TR-7 to about 90w out, but I'd rather set it back up where it should be and be able to adjust it better.

I had a parts list at one time, but can't find it.
Thanks,
David

David -

That's another of those "unobtanium" parts. Many have been destroyed by the failure of R11 in the power supply, which puts +2500V across the pot element.!!

IF I had a bad one, I'd replace it with a linear 500k pot with a 120k resistor across the element. The result is a 100k resistor with the pot wiper at the top, (500k in parallel with 120k), and at half rotation it would be 80k. At 3/4 rotation it would be still be 62k. A 500k pot with an audio taper would be an interesting experiment as the two "tapers" would be opposing each other!!

Well found my problem, I was using a alligator jumper, which was adding inductence, soldered in a short piece of wire and was able to tune the overcoupler!

The receiver is now working fine....maybe not as sensitive or selective as the k3, but a lot more pleasant to listen to on 75 or 40!

From: q2audio@rocketmail.com
Topic: 3174 Message: 3174

Hi,

I have a TR-4 that seems to be out of alignment (doesn't seem to receive much of anything besides AM), possibly a failed part in the receive section? I bought it used, don't know the history but it looks pretty clean. I have rebuilt the power supply with a "kit" (replaced the bias pot as well, rebiased finals per the manual). I am an electronics tech with 17 years of experience but not with RF or radio so this is a new adventure for me.

If anyone has the patience to help me out, please email me directly.

Thank you and 73,

Tim

Tim -

Receiving only AM would indicate a problem with the BFO (Beat Frequency Oscillator). Depending upon the s/n of your TR-4, it might have a 6GX6 tube at V16, which generates the BFO signal.

There were eight (8) versions of the TR-4, with various changes. The 6GX6 was used in all, so it would be the first suspect.

What test equipment do you have available?

Topic: 3170 Message: 3177

Thanks Garey.
Well mine still works, I just don't think it works as it should......and as long as the TR7 is dialed down, it should be fine. I also use my Omni VI with it (I have the soft key board in the amp), and of course can adjust the rig output. Never used the TR4C with the amp, but if I did, I think it would work well enough to use, or I could just "load it lighter" as one drake service memo suggested. My supply has had all the updates and a higher wattage R-11....I think at your suggestion...sometime in the past !!

I'm kinda gentle with my L-4B and keep it down around 500 on the plate when tuning, either using the ALC control or the Omni VI output adjust.

I've been thinking about building a three rig switch for the two drakes and the TT. It would need to switch the ALC lines on the two drakes, as well as the key line. Then the Omni is just the key line. Well....its on my bucket list!! Hi Hi.

Garey,

Thanks for the reply.

I have available here:

20MHz O-scope (100Mhz available at work)
Fluke 187 DMM
Radio Shack 22-306 freq counter (should be accurate enough)
A very basic Tenma RF gen - it might have AM modulation.
HP Audio oscillator
HP DC power supplies
200W 50 ohm dummy load

My TR-4 does have the 6GX6 at V16 per the schematic that I have. I did go through the schematic and I ordered all of the values of cathode resistors used in this radio. I know from my work on tube audio equipment that those tend to go bad slowly over time. I wanted to have them on hand in the event I needed them. I have a spare relay as well. I did check all of the tubes and they checked O.K.

Tim

anything besides AM), possibly a failed part in the receive section? I bought it used, don't know the history but it looks pretty clean. I have rebuilt the power supply with a "kit" (replaced the bias pot as well, rebiased finals per the manual). I am an electronics tech with 17 years of experience but not with RF or radio so this is a new adventure for me.

3179. Orlando FL Hamcation Info

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-01-31 14:13:53 UTC
From: Ken Simpson, W8EK
Topic: 3179 Message: 3179

Orlando FL Hamcation Information:

The Orlando Hamcation is less than two weeks away. It will be held from February 12 thru February 14, but much of the activity starts on Thursday, February 11, when most of the tailgaters set up. If you have not made your plans to attend, you need to do so now. Florida is the place to be in February!

Info can be found at
http://hamcation.com/default.html
There is a lot of information at this web site, so be certain to check all of the special areas.

At the present time, there are a few tables still available in the swap building. All of the wall spaces and end caps have been taken. If you want more than one table together, get your reservation in NOW. Having a table inside the building, instead of outside in the tailgate area, protects you (and your equipment) from the weather, and only costs $10 more for the entire weekend. Please e-mail hamcation@... to make reservations or get more information.

Everyone knows that there are many other activities in the central Florida area, so be certain to bring the XYL. Hamcation will also have YL activities, and of course many are now hams, so will enjoy Hamcation as well. The bottom line is "Bring the entire family."

Advance registrations are running considerably ahead of last year, so this promises to be another large (10,000 plus hams) hamfest. To put it another way, don't stay home because you think attendance might be down due to the economy. It does not look that way.

See you there!

Thanks.

73,

Ken, W8EK

3183. TR-3 meter action

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-02-06 00:32:56 UTC
From: captcurt2000
Topic: 3183 Message: 3183

For those with experience using a TR3..I have one here that shows wild meter bounce..like NO damping on the movement. Huge interaction between the two movements. They work fine steady state, but a normal s-8 CW signal for instance will get the s meter swinging from 0 to the right peg and will excite the ammeter to half scale swings also.

All else seems to be working..AGC appears to work.

The TR4 I have does not do this...it has the normal slight induced movement of the opposite meter and the S meter behaves like all the 4 line meters.

Is this a normal thing for the TR3?

Any ideas on where to start looking?

Thanks

Curt

Well, I am puzzled by what you were trying to do. If you posted just a link to a site with the pictures it should have come through. If you tried to post an actual binary file (jpg or similar) to the list my bet is that it was blocked by the list settings. An attachment is anything in an e-mail that is not plain text. While formatted test is technically not an attachment it is also blocked by some lists. The rules of the list should tell you if binaries can be sent to it.

3195. Original Drake or Not

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-02-08 18:01:16 UTC
From: captcurt2000
Topic: 3195 Message: 3195

OK. got the pix to load into the album Original Drake or not? in the photo section of the yahoo group.

This is the questionable trimmer on the PTO for a TR3 that would not get all the way up to 5.5MHz and would hit 4.9MHz at about 1/3 of the screw out from end.

Garey suggested that this mmight have been an attempt to put this radio on 11M and I am starting to think that is exactly right. This does not appear to be an original PTO. It is a tube type but has the larger can as a cover. And the PTO mounting holes have been adjusted.

Finally, and I just found this...there were 15pF of caps added to the 9MHz crystal. I'm still looking at that one. I need to check the freq of the 9MHz oscillator to see what it is doing.. Don't see how that could ever work knowing that the crystal filters are at 9MHz. The other goofy thing is that if you wanted to work on 11M I think you would need the PTO to go higher not lower.

Perhaps this is why it was collecting dust somewhere..a failed conversion job..serves them right if that's what they were doing.

I removed the screw and the jumper to the nut in the PTO and the PTO is now running the way it should..4.9 to 5.5 with a little at both ends to the stops.

The trimmer addition in the photos looks pretty good. the insulator stock has very nice, cleanly punched holes for the screws etc but is hand cut on the outsides so I'm still not sure.

Is this Drake or Not?

Cheers,

Curt

Curt -

Nope, not Drake. I have to admit it's creative, but the PTO has four mounting screws, one in each corner.

Can't say I know what was being attempted, but it ain't stock!

The 9 MHz crystal may have drifted up in frequency with age, and the added caps were an attempt to pull it back down to 9.000 MHz.

3202. Drake T-4XB Low power output

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-02-11 03:13:21 UTC
From: kf0hr
Topic: 3202 Message: 3202

Hi, Need some help with my Drake T-4XB transmitter. This transmitter has been sitting unused for 15 years. I brought it up to see if it worked before cleaning and using Deoxit5. It put out 100+ watts into the dummy load. Cleaned all switches, contacts, tube pins and Deoxit5 same. Worked OK after cleaning then lost most of the output. It dropped to about 10 watts? RF is same at 12BY7 driver tube on the plate pin 7 as it is going into pin 2 of the final tube. A little loss is shown at the antenna connector at rear of TX. Checked all voltages and ohmed out finals. All look close per manual, tried different final tubes known good tested in my T-4X, compared readings with my T-4XB and my T-4X. All look to be close to same? Why the low RF output? Then out of the blue I get back my 100+ watts output for about a day. Then it dropped back to the 10 watts output? Replace the disk caps on the finals with no change. Final Cathodes drop to .1 volts in tune position. Lost as to what is holding the transmitter finals from full power? One more problem is my TX relay closes and don't release all the time when I have the low 10 watts output?
Thanks, Terry KF0HR in North Dakota

Terry -

Check value and condition of R23, R24, R26, R30, R31 and R36. They sometimes crack "invisibly" making various resistance levels. Give each one a little tug or push as well. Less likely, but possible is C61.

> Hi, Need some help with my Drake T-4XB transmitter. This transmitter has been sitting unused for 15 years. I brought it up to see if it worked before cleaning and using Deoxit5. It put out 100+ watts into the dummy load. Cleaned all switches, contacts, tube pins and Deoxit5 same. Worked OK after cleaning then lost most of the output. It dropped to about 10 watts? RF is same at 12BY7 driver tube on the plate pin 7 as it is going into pin 2 of the final tube. A little loss is shown at the antenna connector at rear of TX. Checked all voltages and ohmed out finals. All look close per manual, tried different final tubes known good tested in my T-4X, compared readings with my T-4XB and my T-4X. All look to be close to same? Why the low RF output? Then out of the blue I get back my 100+ watts output for about a day. Then it dropped back to the 10 watts output? Replace the disk caps on the finals with no change. Final Cathodes drop to .1 volts in tune position. Lost as to what is holding the transmitter finals from full power? One more problem is my TX relay closes and don't release all the time when I have the low 10 watts output?

Dale,

Someone once said that the only stupid question is the one not asked. That's true I suppose, except for my question. No, I don't have a 160m crystal. How dumb is that?

I've had this receiver for several years, but never worked on 160m. I use my Kenwood TS-520S for that. This evening, I just thought I'd do a comparison of the two rigs. That's when I discovered the R-4A was dead. After reading your answer, I looked at the manual and right there on page 3 it says, "80-10m ham bands are stock; others require crystals to be added". I guess I assumed that since 1.5-3.0Mc was one of the band switch positions, that I was good to go. RTFB they told us in the service. I should have listened.

Now I'm off to find the proper crystal for 160m. Thanks for your help. I'll be expecting my dummy-of-the-Month award in the mail shortly.

Garey,

Thanks for the tips to find the T4XB low output. Checked the parts you listed with all looking OK in line? I checked the voltage and resistance per manual. All look close. I did check the voltage when the tranmitter was putting out 100+ watts. Both voltage readings look same? I show same RF level at pin 7 of dirver 12BY7 tube as I do on the finals. No loss to speak of? I do show less RF at the antenna jack. My thought is every thing up to the finals is working? I show same RF level on both my T4X and T4XB. I have checked so many time I forget where I am at in the testing HI HI Maybe change to the talking mode instead of trouble shooting. Maybe if I let it site for a couple days it will start to work again. I had to remove the covers again as I thought I had the T4XB ready for a QSO.

Lost on the LOW RF with 7 new inches of snow.

Terry -

OK. Well gotta start somewhere in the process of elimination! :-)

What happens to the plate current at both levels?

Have you tried swapping Final tubes?

What is the Final Screen voltage at "low power"?

AF4K sells crystals for the Drake receivers. Look on his web site under the "HC6/U listings for Drake. You might consider getting crystals for 30M, 17M, 12M, and the bottom 500 Khz of 10m while you're at it. I've had good luck with Brian's crystals.

Hello Randy,

If you still need a 12.6 Mhz crystal, I have for sale, $15.00. I also have a few other 4-line crystals if needed.

Tnx & 73, Bill

Garey,

My T4XB
Final tube
Rx Plate is 722 volts TX at 10 watts is 685 volts
Rx Pin3 is 149 volts TX is.39 volts
Rx screen is266 volts and drops to 245 volts in TX
idle Bios is .07
Plate current at 10 watts is .15 when I was TX at 100+ plate was over .3 amps.
Just checked RF probe at 12BY7 pin 7 plate is 30 and at 6jb6 pin 2&6 strip I have 30 (same)
I have checked voltages against my T4X and different power supply with same results. Also tried known good final tubes, the TX has put out 100+ watts 2 times but has dropped back to only 10 watts again.
This transmitter should put out 100watts. What is holding it back???

Thanks,

Terry KF0HR in North Dakota with a foot of new snow ..WOW

OK. Have you checked R32 and R33? It sounds like one of the Final tubes
is going 'out of circuit'. You're getting about 1/2 of normal output
current, and the Pi-Net is set to see the plate impedance of two tubes,
but only one is working. Check the voltage at both Pin 3s to see if they
are about the same.

350 mA is about normal for two tubes, or about 175 mA each. You should
see about 1.4 VDC at each Pin 3, and a little less than 1 VDC at the
feedthrough C60.

All look close per manual, tried different final tubes known good tested in my T-4X, compared readings with my T-4XB and my T-4X. All look to be close to same? Why the low RF output? Then out of the blue I get back my 100+ watts output for about a day. Then it dropped back to the 10 watts output? Replace the disk caps on the finals with no change. Final Cathodes drop to .1 volts in tune position. Lost as to what is holding the transmitter finals from full power? One more problem is my TX relay closes and don't release all the time when I have the low 10 watts output?

Just checked the voltage at both sides of R32 R33 Both are same with .6 and 1.8 volts on both tubes. Maybe I lost a tube, will try spare set of final tubes. Thanks...Terry KF0HR

From: w5rkl
Topic: 3202 Message: 3216

I have a similar intermittent power output problem. It occurs on all bands.

If V1 or V10 are moved either by vibration or your finger, RF output drops from 100 watts to 10 watts. Tapping on the chassis or cases typically brings the output back to 100 watts. Output does come back "some times" if V1 and/or V10 are moved by my fingers.

I have visually inspected V1 and V10 sockets and found nothing lose or shorted. My next step is to check the crimp pins on the PC board mounted vertically next to V1 and V10 to see if the connections are intermittent.

You might tune up the T4XB to full output then place mode switch in CW and key up into a dummy load. Move V1 and/or V10 to see if RF output falls back to 10 watts. If so then you have the same problem I have which I have not yet found the source of the problem.

Just a thought.

3217. Re: Drake T-4XB Low power output

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-02-13 19:27:20 UTC
From: captcurt2000
Topic: 3202 Message: 3217

OK..here is another question. He indicated he is seeing about 30V of RF drive..was that RMS from the RF probe?

I saw someone post that it only took 40-50V P-P to drive these rigs' finals but that seems like half of what I would guess.

If the Bias is sitting at (nominally) -60, it seem like it would take 120 P-P to get the finals to draw grid current and thus ALC??

I hav a couple of TR's and the good ones have over 100 P-P on the grids of finals measured directly with a scope on 80M. The measurement gets iffy above that due to probe loading--but this is a value that makes sense me..The TR that have low output all show in the neighborhood of 30-50V P-P there.

Am I missing something?

Thanks

Curt

3218. Re: Drake T-4XB Low power output

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-02-13 19:43:40 UTC
From: kf0hr
Topic: 3202 Message: 3218

Mike,

The problem you have sounds a lot like my T4XB 100 to 10 watts output.
I have moved the tubes around but no luck to get the full power back.
I have been thinking about the AGC also???
Will let you know if I can ever find this problem.
All my voltages say the Final tubes should put out full power.
So I need to look at other areas maybe?

Thanks Terry KF0HR in North Dakota

> > >>>>> Hi, Need some help with my Drake T-4XB transmitter. This transmitter has been sitting unused for 15 years. I brought it up to see if it worked before cleaning and using Deoxit5. It put out 100+ watts into the dummy load. Cleaned all switches, contacts, tube pins and Deoxit5 same. Worked OK after cleaning then lost most of the output. It dropped to about 10 watts? RF is same at 12BY7 driver tube on the plate pin 7 as it is going into pin 2 of the final tube. A little loss is shown at the antenna connector at rear of TX. Checked all voltages and ohmed out finals. All look close per manual, tried different final tubes known good tested in my T-4X, compared readings with my T-4XB and my T-4X. All look to be close to same? Why the low RF output? Then out of the blue I get back my 100+ watts output for about a day. Then it dropped back to the 10 watts output? Replace the disk caps on the finals with no change. Final Cathodes drop to .1 volts in tune position. Lost as to what is holding the transmitter finals from full power? One more problem is my TX relay closes and don't release all the time when I have the low 10 watts output?

Curt -

I think he is referring to an RF Probe, which typically measures an RMS value. Terry didn't specify a band, and ~45V RMS would be in the ballpark. I suspect loading from the probe is a factor here. I haven't specifically tried 80M, but on 40M a 10X probe shows 130V p-p, in TUNE with the GAIN set to just below ALC. With typical BIAS voltage around 60 - 65 volts that's what I would expect also!

But that is a good question Terry, what band are you making your measurements on? Is it the same on several bands?

Curt,
This is Terry in North Dakota witht the T4XB that is only at 10 watts output. The 20 to 30 volts is RMS with Heathkit RF probe so only for referace of RF. Something is holding my TX tokeep the finals from 100 watts. I checked my T4X with my RF probe to see what a working TX sees with my RF probe. It shows the same amount of RF getting to the finals with 100+ watts output.

Thanks, Terry KF0HR in ND

Hi Mike -

Haven't heard from you in a while! I can see how V1 might be affected,
but I don't see V10 causing this kind of problem.... interesting.

R94 may be a 'common' part, if it were cracked or ? It's right at the
top of that board. Mounting screws for that board?

This is Terry. Just checked the T4XB on 80M for 25 volts RMS, 40M for 22 volts RMS, 20M for 18 volts RMS. The 10 watts output drops off some as I go up in Freq. I just hooked up my spare T4X and checked for drive at the finals with the RF Probe. It show 80M 50 volts RMS. So my T4XB has low drive. I don't know why this has changed? You know how it goes when you start checking so many things. Also maybe the transmitter is changing? Old test equipment? Now I need to back up again.I might not have enough drive to get 100+ watts. Time to start over and check everything again.
Thanks for the Help Terry KF0HR

Gary, I have your disc for the B series. First of all, I
very strongly recommend that anyone who has this line get
the disc.
In the pictures of the chassis I noticed that the ring
modulator connections to the AVC and output to the IF amp
seem to be reversed from the way mine is connected. I wonder
if this is an optical illusion or if mine is wired
differently or if some previous owner changed it. In the
illustration the AVC lead (black wire from the nearby
circuit board) is connected to the far bottom pin (right
most pin) of the can while the output to the grid of the IF
is connected to the left most pin so that the two cross.
Mine is wired with the black lead going to the left pin and
the right pin going to the tube grid. Which is correct or
did the factory use both arrangements?
I don't think this has anything to do with my current
problem but it might prove useful to know.

Curt -

I think he is referring to an RF Probe, which typically measures an RMS value. Terry didn't specify a band, and ~45V RMS would be in the ballpark. I suspect loading from the probe is a factor here. I haven't specifically tried 80M, but on 40M a 10X probe shows 130V p-p, in TUNE with the GAIN set to just below ALC. With typical BIAS voltage around 60 - 65 volts that's what I would expect also!

But that is a good question Terry, what band are you making your measurements on? Is it the same on several bands?

FWIW, an oscilloscope with a high impedance probe (10X type) is a good tool for checking RF levels. Or course it measures peak to peak. Voltmeters using single diodes are not linear and may indicate something approaching true RMS at low voltages but will measure peak voltage at higher levels. Most meters are calibrated in the sine wave RMS equivalent of whatever they measure. Some have separate scales for the lower voltages. The more common electronic voltmeters use diode bridge rectifiers which put out average values of voltages. The meters are again usually calibrated in the RMS equivalent for a sine wave. Because the meter scales of either type are calibrated to show something other than what is being measured one can get quite large errors for waveforms other than pure sine waves. In particular peak reading meters can vary where there are harmonics, the amount of the error depending on the phase as well as the

amplitude of the harmonics. This may or may not be
significant in checking something like the RF levels in the
driver stages of a transmitter but should be kept in mind.
The scope will, of course, indicate the actual waveform.
Most scope probes have built-in 10X deviders which also
increase the input impedance when in the X10 position. Most
scopes have about 10 megohm impedance, which means 100
megohm when the probes are set for X10, enough so that
loading of the measured circuit is not often a problem.
I am trying to track down a problem with my own T-4XB.
I had it working well and was looking for an apparent
variation in audio gain when I slipped making a measurement
of the power supply. Whatever I did blew the filament fuse
and when I replaced it the drive was down to practically
nothing. I've gone through the tubes and replaced a couple
but to no avail. I am still working on this and am not quite
ready to yell for help yet.

OK now I have 100+ watts output with my T4XB. Was going to see how much RF was at tube V3 6AU6. Popped in tube extender and my RF jumped to 100+ watts output? Maybe moved something with the tight fit of the tube extender. Might have a bad Pin on the tube socket? Or my RF probe loaded down the tube when testing and it started to work again? Will up date when I find the problem. I show 55 volts RMS on my RF probe at the final tube on the pin 2-6 strip. With the 10 watts out it was at about 20 volts RMS with RF probe. Will have to look at the RF with scope to see how that works.

Thanks for help to this point.

Terry -

OK. 50V RMS is about right. If you're only getting 25 VRMS the Final tubes are not being driven to full power. So the problem is "further upstream". What RF voltage do you measure on the Grid of V4?

> This is Terry. Just checked the T4XB on 80M for 25 volts RMS, 40M for 22 volts RMS, 20M for 18 volts RMS. The 10 watts output drops off some as I go up in Freq. I just hooked up my spare T4X and checked for drive at the finals with the RF Probe. It show 80M 50 volts RMS. So my T4XB has low drive. I don't know why this has changed? You know how it goes when you start checking so many things. Also maybe the transmitter is changing? Old test equipment? Now I need to back up again.I might not have enough drive to get 100+ watts. Time to start over and check everything again.

Hi Gary,

Hope you are doing well.

I suspect the only reason V10 affects the RF output is it's physical location and filament wiring to V1. Moving V10 can cause movement in V1 wiring. V10 doesn't actually cause the RF to drop but the physical movement of the wiring does.

If the problem occurred in sideband then I would agree, R94 may be the source. However, the problem occurs in CW mode. When it happens, it doesn't matter what mode the xmtr's in, RF output is down to 10 watts at most and that's with the GAIN pot set to maximum. I don't normally set the GAIN pot that high but to check, I set it at maximum but there was no change.

I can see V1B causing a significant reduction in RF being fed to V2 from the balance modulator if there's an intermittent short to ground in V2B's circuit. I'll have to check it to see. More than likely the close proximity of V10 to V1 and the filament wiring may be causing the intermittent connections in V1 that is causing my problem.

I also know the balance modulator transformer, T1, has an intermittent connection inside the can. This is not the same problem caused by moving V1 or V10. If I touch T1's adjustment the RF output drops to zero. Touching V1 or V10 the output drops to 10 watts. Either way, I have 2 problems that need fixing.

Always something with these old rigs. Love working on them.

I did check the voltage when the tranmitter was putting out 100+ watts. Both voltage readings look same? I show same RF level at pin 7 of dirver 12BY7 tube as I do on the finals. No loss to speak of? I do show less RF at the antenna jack. My thought is every thing up to the finals is working? I show same RF level on both my T4X and T4XB. I have checked so many time I forget where I am at in the testing HI HI Maybe change to the talking mode instead of trouble shooting. Maybe if I let it site for a couple days it will start to work again. I had to remove the covers again as I thought I had the T4XB ready for a QSO.

It put out 100+ watts into the dummy load. Cleaned all switches, contacts, tube pins and Deoxit5 same. Worked OK after cleaning then lost most of the output. It dropped to about 10 watts? RF is same at 12BY7 driver tube on the plate pin 7 as it is going into pin 2 of the final tube. A little loss is shown at the antenna connector at rear of TX. Checked all voltages and ohmed out finals. All look close per manual, tried different final tubes known good tested in my T-4X, compared readings with my T-4XB and my T-4X. All look to be close to same? Why the low RF output? Then out of the blue I get back my 100+ watts output for about a day. Then it dropped back to the 10 watts output? Replace the disk caps on the finals with no change. Final Cathodes drop to .1 volts in tune position. Lost as to what is holding the transmitter finals from full power? One more problem is my TX relay closes and don't release all the time when I have the low 10 watts output?

Richard -

Glad you're finding the CD useful!

I can't find my "other" T-4XB, so can't speak to the "standard"
question, but I just opened up model for the CD, and it is indeed wired
as you thought. Another interesting fact is that C9 is NOT connected
across the secondary as shown on the schematic, but is connected from
the tube Pin to chassis. Looking closely at this one, all appears
original, and no burned insulation in a very tight spot, so I think it's
safe to assume that it is factory.

I think I know where the other transmitter is.... :-) Lemme check!

Terry -

Cool, Progress!! You should see about 3 V p-p on the Secondary of T2,
and about 3 V p-p on the "top" of the Secondary of T3 (C16) of Carrier
Osc signal, and about 3V p-p on the "bottom" (R15) of T3 of the PreMixer
signal. You should have about 6 V p-p on the Grid of V4.

> OK now I have 100+ watts output with my T4XB. Was going to see how much RF was at tube V3 6AU6. Popped in tube extender and my RF jumped to 100+ watts output? Maybe moved something with the tight fit of the tube extender. Might have a bad Pin on the tube socket? Or my RF probe loaded down the tube when testing and it started to work again? Will up date when I find the problem. I show 55 volts RMS on my RF probe at the final tube on the pin 2-6 strip. With the 10 watts out it was at about 20 volts RMS with RF probe. Will have to look at the RF with scope to see how that works.

Cheesh, I can't even get a trophy. This hasn't been my week.

I know that International Crystal Mfg. is perhaps the favored place to get crystals for our rigs, and I know that this subject has been broached before, but in the interest of completeness, are there any new places that are now highly though of for Drake crystals? Obviously I need a couple of 12.6 Kc crystals; one series resonant for the R-4A and one parallel resonant for the T-4X.

Thanks in advance for any comments and 73 all.

Me again! I found the other T-4XB, and it is wired exactly like the one in the CD. So yes, they DO cross over, and C9 is wired from the tube pin to ground. Swapping them the way yours is would invert the phase, but that shouldn't make any difference. Maybe someone just felt rebellious that day!! :-)

These are both the late version, 17 and 19k s/n. If yours is before 16159 there may have been a change.

Gary,

No not yet. I want to get the V1/V10 problem fixed first then tackle T1. Other than those 2 problems the T4XC is doing fine, especially after rebuilding the AC4 supply.

I'll keep ya posted.

Thank you very much for taking the trouble of looking.
I am fighting another problem with this transmitter but
I wonder if the mis-wiring might have caused the nulling
problem I had. When I figure out the other problem I will
try it. Right now I have to work at it in fits and starts
because of time constraint. Work interferes with life a lot.
This particular TX has had a lot of problems but has
certainly taught me a lot about Drake stuff. I am an
old-fashioned type who beleives that amateurs should know
how to repair their own equipment and be able to build at
least rudimentary equipment.

Hello list,

My Drake T4XB transmitter relay is hanging up once and awhile?

How do I tell if it is the relay circuit or the relay itself?
When it sticks a love tape(Valentine's day) on the TX releases the relay back to receive mode. I don't quite understand the relay circuit? I see the 250 volt on one side of the relay. The other side goes to the V10b 6EV7 tube. Does the 6EV7 tube go low to pull in the relay? How about the diode D9 and D12, what are they doing in this chain?

Thanks Terry KF0HR in North Dakota

3238. T-4X Sidetone in Spot

From: russellhulett
Topic: 3238 Message: 3238

I have a T-4X paired with an R-4 in "separate". When switched to spot on the Tx, I hear the sidetone as well as the VFO signal. That is, there is a constant frequency tone heard no matter the setting of the Tx VFO. Of course, when the Tx is moved to the received frequency, much louder tone is heard. Is this likely a Tx switch problem or something else?

Martin -

First check the Carrier Oscillator frequency. It should be 9.00000 MHz
in SSB MODE and 9.0009 or so in CW.

If you don't have a counter, you can check it with a general coverage
receiver.

Alternatively, note the position of C6, (you can access it through the
hole in the rear chassis wall, on the left side,) for the adjustment.
Using an insulated tool, adjust per the manual, Section 5-9.

If this doesn't resolve it, let us know!

Usual cause for this is a gassy 6EV7. Typically it gets worse after the transmitter is on for a while.

Yes, the 6EV7 acts as a switch. When the grid is biased negative, the tube is cut off, and no plate current flows. When the grid is driven positive, the tube conducts heavily and enough plate current flows to pull in the relay. The plate doesn't go to near 0V like a transistor switch, but pulls enough current through the relay to cause it to close.

D9 and D12 develop the ANTI-VOX bias to shift the 6EV7 grid more negative, raising the "trip" threshold.

You're probably hearing the sidetone. IF you have not replaced C132,
try bridging a good cap across it.

Garey,

Thanks for this last post. Really helps me with working on this classic transmitter. I did try changing out the 6EV7 tube with same results on holding the relay in some times. My Drake Twins have been on for the past 4 hours. Had a rag chew for ann hour,the relay never stuck. Now playing with CW and it got hung up again. Light tap on cabinet frees it up. Going to look at the relay with a good light. Might see something?

Thanks for the explanation on how the relay, 6EV7, and the diodes work in this circuit. Working on the old radios is not only fun but I am learning something about how they work. Thanks, Terry KF0HR in North Dakota

From: kf0hr
Topic: 3243 Message: 3243

Hello List,

Here is a strange one, anyone eles had this happen?

My MS-4 speaker hooked to my Drake R4B receiver had low audio. So I have been running a spare 4 ohm speaker for testing. Well pulled out the power supply from MS-4 cabinet. Installed new 4 ohm speaker, replaced the AC supply into cabinet. The new speaker had same low audio?
When removing the AC supply box from cabinet my audio jumped up loud and strong just as soon as the power supply was away from speaker cabinet? I see about 1 volt AC between the speaker cabinet and power supply. Must be some leakage in the power supply? Any ideas on why grounding the power supply to speaker cabinet does this?

Thanks Terry KF0HR in North Dakota.....

OK. When it "sticks" in CW does the receiver stay muted?

I believe you have replaced C129.

Check the relay for mechanical interference from wiring.

If you have another 6EV7 it's worth a try. Even NOS tubes can be gassy
after 40 years!!

Garey,

I just repalced the C129 dual cap with new caps. Still hangs up the relay. I had tried a different 6EV7 tube out of my T4X(worked OK). Went out to my radio storage shack and found a GE6EV7 new in the box. Inserted the new tube and no relay sticking. Also the delay sets real nice now. So will put the leaky tube into my tube tester and see if it can show the leak? I had a leaky tube in my Collins KWS-1 a couple winters ago. Should have tried more than one tube...

Thanks, Terry KF0HR in North Dakota

OK, great! Just another of the many reasons I advise against "shotgun" replacement of all tubes in a radio at once!

They're called "gassy", and in some cases that's the actual mechanism. The 6EV7 and the 12BA6 suffer from "grid emission", which is when material boils off of the cathode and is deposited on the grid. Then when to grid heats up, that material actually emits electrons and drives the grid more positive. In the 12BA6 IF tubes it alters the operating point of the tube, which unbalances the S-Meter. This is why S-Meters "drift" over hours of operation, either positive or negative depending upon which tube is "gassy". In the 6EV7 it presents as altering the grid voltage a little, enough to hold the relay in, but not enough to PULL it in. The longer the transmission, the hotter the grid gets and the more it shifts.

Up and running!

Terry, some questions about the strange MS-4
1. do you use the rca plug/connector in the speaker case? could problem be in that cable?
2 The diagram that I saw of the AC-4 show some strange use of the 12pin power connector?
3. Did ohm meter of the cable to radio show any problem??
4. Cant see much there , but cable wire and connector. ....May account for the intermittent when changing speaker..

Martin -

First check the Carrier Oscillator frequency. It should be 9.00000 MHz
in SSB MODE and 9.0009 or so in CW.

If you don't have a counter, you can check it with a general coverage
receiver.

Alternatively, note the position of C6, (you can access it through the
hole in the rear chassis wall, on the left side,) for the adjustment.
Using an insulated tool, adjust per the manual, Section 5-9.

If this doesn't resolve it, let us know!

Ken,
My MS-4 speaker had a head phone jack and toggle switch installed on the front panel. I said HAD.....it was wired wrong and pulled the speaker down when the power supply is installed. Will have to see how it is setup with plug and toggle switch. Must have center pin of speaker cable shorting to ground?

My Drake twins are coming back to life after 15 years in closet. I can see why past owner put then away. They needed TLC from a Drake fan.

Thanks for the tips here on the Drake list.

Been long time now with no packet radio here. My local digi became the APRS KF0HR-7

Thanks, Terry KF0HR in North Dakota

low audio?
> When removing the AC supply box from cabinet my audio jumped up loud and strong just as soon as the power supply was away from speaker cabinet? I see about 1 volt AC between the speaker cabinet and power supply. Must be some leakage in the power supply? Any ideas on why grounding the power supply to speaker cabinet does this?

Thanks Terry, good deal, always wanted some Drakes!.
Hope you get all the kinks worked out, I am still tinkering with Heath HW-101 and some ole Atlas.
Most have gone to APRS..Here,.for me too senior, i guess, dont care where I have been or going!! hi hi

Those old Drakes are NICE.

Ken,
My MS-4 speaker had a head phone jack and toggle switch installed on the front panel. I said HAD........it was wired wrong and pulled the speaker down when the power supply is installed. Will have to see how it is setup with plug and toggle switch. Must have center pin of speaker cable shorting to ground?

My Drake twins are coming back to life after 15 years in closet. I can see why past owner put then away. They needed TLC from a Drake fan.

Thanks for the tips here on the Drake list.

Been long time now with no packet radio here. My local digi became the APRS KF0HR-7

Thanks, Terry KF0HR in North Dakota

Hello Gary
Output is now ok on 80 40 20 2 sidebands idem
on 15 130 watts on tune mod and 15 on cw
on 28 nothing at all.
All switch in the T4XC are very dirty.
Carr osc reading 5.645 C6 make nothing and top resistance also no effect.
Martin
Tnx for your help Gary

Martin -

First check the Carrier Oscillator frequency. It should be 9.00000 MHz
in SSB MODE and 9.0009 or so in CW.

If you don't have a counter, you can check it with a general coverage
receiver.

Alternatively, note the position of C6, (you can access it through the
hole in the rear chassis wall, on the left side,) for the adjustment.
Using an insulated tool, adjust per the manual, Section 5-9.

If this doesn't resolve it, let us know!

OK. Sorry, I was thinking TR-4 when I said 9.000 MHz.

The Carrier Osc should be 5.644999. on SSB and 5.645 on CW. Did you try the balancing method in the manual Section 5-9? The frequency is VERY critical, so unless you have good counter the manual method is best. If you visualize the two filters as the "tops" of the letter "M", it's very important that the Car Osc be exactly in the "valley" between the two humps. The counter or receiver will ensure that it's not outside of the humps on either side. C6 only moves the Car Osc a few hundred Hz either way.

The method of carrier generation is the same on all bands, so I don't know why you would have low output on CW on only ONE band. For CW operation, the Car Osc is shifted up about 900 Hz so that it is WITHIN one of the humps, and a DC current is applied to the Balanced Modulator diode ring to "unbalance" it to generate the carrier that is then amplified by the transmit chain. You MAY have to turn the XMIT GAIN control considerably higher on 15 and 10M to get enough drive. If the XMIT GAIN control has to be advanced much more than 2 o'clock, you may have a resistor R104 that has increased in value from age.

It's also possible that dirty switch contacts are limiting the current applied to the Bal Mod diodes. The current goes through contacts on the rear of the fourth section of the MODE switch. Clean with DeoxIT liquid (D100L) only, do not spray and do not use any cotton buds or other tools on the contacts. Let the cleaner and rotating the switch through all positions do the cleaning. If all you have it DeoxIT or other spray cleaner, spray some in a small cap and apply the liquid directly to the contacts of the switches.

Curt -

It's not really "open", what happens is that the electrolyte dries up after "only" 40 years or so and the Equivalent Series Resistance (ESR) increases, which essentially puts a resistor in series with the capacitor. When this happens, the audio tone from the MIC AMP (V9a) sidetone oscillator is coupled "around" the diode (D8) switch that keys the sidetone so sidetone all the time, possibly getting louder when the transmitter is keyed, but still present as a sort of "backwave" when it's not..

I want to make sure I'm not misleading you because of language differences.

In TUNE mode the XMIT GAIN must be turned Clockwise, and will "top out"
around 40% of full rotation.

The XMIT GAIN must be turned Clockwise to half or three quarters
rotation for CW, further Clockwise on CW!

Topic: 3260 Message: 3260

My bias voltage has been changing so I decided to monitor it more
closely. I ran wires outboard from R59 (new 3.3 ohm resistor)to
a DMM . Knowing it was going to rise I set the Bias to 50mA or
using the formula (.050 x 3.3=.165 VDC) OR 165 Mv.
It will run for several days at 50-65 mA and then will rise
one day for no apparant reason to as high as 115 mA. And then later or the next day it will be back down to 50 mA.
I noticed as soon as I hooked up the DMM that there is a resting
current on R59 of between .2-.5 mV with no transmit and the transmitter
in the SEPERATE mode. As long as this resting current stays in that
range the Bias is fine, but then it will rise to as high as 3.5 mV.
Sometimes as a result of transmitting (cw) and sometimes it will just
start to rise on its own.
Any ideas on what is causing this or is it normal?
Thanks
WINK

Hello all.
I have a Tr-4 that doesnt have the 34 PNB board and it has no provisions for the board to be installed. It is the older TR-4 that has the newer VFO knob but no NB switch.
isit possible to install the 34 PNB or some other NB circuit into the TR-4?

I cemented a broken wafer switch on a Hammarlund
SP-600. The switch is a small one that is operated by the
band switch in going from single to double conversion. I
cemented it twice, once using super glue and a second time
using fast settng epoxy. Both worked. It glued it twice
because I broke it again. The physical location of the
switch is such as to make it vulnerable. The wafer is made
of Bakelite.
The wafer switches in the Drake RX and TX are larger and
of thinner material so I can't be sure the technique will
work there but it is certainly worth trying.

Wink -

Two possibilities come to mind..... Does the transmitter put out 130W
or so in either situation?

If not, there may be a problem with the Screen or Cathode resistors of
one of the Final tubes, since your current ratio is about 2:1.

If it IS working either way, then you probably have a heater/cathode
leak/short in one of the following tubes, V2, V3 or V7. This may be the
cause of your "phantom" current, and when the tube get hotter it shorts
"more better"! There is a hard relay contact to ground the bottom of
the shunt resistor, (R59), so ANY current present is the result of
"leakage" somewhere. You could pull those tubes out one at a time
while you are seeing your phantom current to see if it kills it.

It will work with the 5 minute epoxy if the material is clean and dry and if
you "V" out the cracked line with a Dremel engraving bit to give something
for the epoxy to fill. Also, build it a little thicker and spread out away
from the break.

Garey,
Yes transmitter puts out 130+ watts either condition.
I will check V2, V3, & V7 and let you know.
Thanks for the tip.

Generally speaking, I avoid any kind of "quick-set" epoxy like the plague. It
just doesn't seem to hold up as well over time. Standard overnight cure JB-Weld
is what I use, for all sorts of glue jobs.

Sorry to be disagreeable but having used both (and many other) adhesives
(many times) when it comes to repair of plastics or composites which include
bakelite, fibreboard, fibreglass etc the 5 minute high strength epoxy is my
repair of choice. It has never failed me when JB has. Plus, I know the epoxy
product will be ok where rf is present.
Usual disclaimers apply
IMHO
YMMV

No need to be sorry. YMMV, as they say. I dig quick-set epoxy out of camera housing parts every day at work with a dull exacto knife. And this isn't the cheap hardware store stuff, either. I have also seen it change color and literally peel off of surfaces over the years.

I agree with you on the "quick-set" epoxy, but isn't JB Weld at least
somewhat conductive? With the black color I would expect some carbon
black is present.

Not sure on that one, Garey. It's possible, although I have not had any problems so far. But I don't generally use it in applications where there is the opportunity for a conductive path anyway, so maybe I just haven't encountered it. I have seen "steel filler" epoxies that do have a metal content, but again, I don't use them on parts with moving electrons.

On occasion when I have a small job that needs to be well glued I'll use either the gel or liquid forms of super-glue BUT the trick is to set it immediately w/ "Zip Kicker". It's an accelerator for super-glue products & causes them to cure just abt instantly.

Ur results may vary,

Butch KA4MIC

Garey,
I pulled V2,V3, and V7 none of them made phantom current go away but
pulling V2 made it go up so I replaced V2. Still have same problem,
Phantom current is there and rises after a while.

Wink -

Hmmmm. That's not much leakage, but the fact that it increases by an
order of magnitude "sometimes" ....

What happens if you put the TRANSCEIVE switch in SPOT?

3277. Re: [DrakeRadio] TR-4 noise blanker

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-02-16 16:24:31 UTC
From: Garey Barrell
Topic: 3261 Message: 3277

Eric -

Drake offered the 34-NB Noise Blanker at one time. It consisted of a card almost identical to the PNB-34, along with mounting and installation pieces. It was turned on and off by a lever (similar to the RF GAIN lever) that was located behind the PLATE control knob.

So yes, the 34-PNB "can" be installed by removing the plug at the bottom and mounting it in the same position using brackets. You'd have to figure some way to add a switch somewhere.

The 34-NB manual with installation info is on my TR-4 CD.

Someone has been asking about replicating the 34-(P)NB blanker board, but ...

From: Garey Barrell
Topic: 3260 Message: 3280

There is so much confusion in the switching for the TRANSCEIVE and MODE switches it's hard to follow. In SPOT position the cathode circuitry for V2 and V3 is disconnected. Possibly a leaky bypass cap on one of their cathode wiring.

I'll have to study some more......

Try different positions of the MODE switch to see if that has any effect......

Changing the MODE has no effect on it either.

Wink

Wink -

Do you have my CD for the C-Line?

73, Garey - K4OAH
Glen Allen, VA

Drake 2-B, 4-B, C-Line& TR-4/C Service Supplement CDs
<www.k4oah.com>

OK. Look at board T7. There is a terminal at the top edge of the board
with a wire to it, and with R28 and R34 right under it.

Lift that wire from the terminal and see if that drops the phantom
current. This lead is the common line for stages V2 and V3 and will
tell us if the leakage is there. TRANSCEIVE switch in SPOT,

From: WINK
Topic: 3260 Message: 3285

There were two wires to that terminal, lifted them and voltage is
still there and higher. It goes to ZERO when on SPOT
same as before.

Wink

Did you separate the two wires from each other?

Check with an ohmmeter from Pin 2 of V7

Unless I'm missing something, (quite possible, my eyes are crossing!,)
you should read "open". Whatever you read, switch from SPOT to any
other position to see what happens.

Yes, It reads open. Now NEW PROBLEM Transmitter keys itself
unless I set CW Delay to MINIMUM.
Wink

Have you replaced C107?

Yes replaced C107 with a can from Hayseed Hamfest.
wink

Well, Garey I'm going to have to get back to it Thursday. I sure thank
you for all the help today. I sure would like to know what changed
and now it chatters and keys itself if the CW DELAY is above minimum
---But I still want to fix the Bias problem too. -- Let's both
think on it a couple of days and I'll get back to you on Thursday.
Thanks a million

Wink -

OK. I assume you have reconnected the things we disconnected today?
The relay tube is biased off by a negative voltage from the BIAS supply,
and turned on by rectifying the sidetone and charging a capacitor to a
positive potential to turn it on. If the GAIN is turned too high, or
the ANTI-VOX is too low it can cause that.

Just keep telling yourself; "We do this for fun!", "We do this for
fun!", "We do this for FUN!" :-)

Garey- The phantom voltage is still there and I can't get the relay
to stop pulling in no matter where I set VOX Gain or Anti Vox. The only thing that stops it is pulling V7 or V10. But replacing them with new tubes does nothing. I don't know what I have done.
I re-checked V7 pin 2 and get 24.2 vdc on it.
That's where I'm at now.

DOES ANYONE KNOW THE VALUE OF THE POTS FOR THE RF GAIN AND AF GAIN CONTROL ON A TR7?

RF GAIN POT IS SHOT.....and nothing in manual, dont have service manual yet.

Any suggestions where where I might find one?
Thanks, Ed

AF = 3K audio taper
RF = 10K

The bad news is these parts are unobtanium. You will have to "roll your own" by finding a similar pot and doing some re-assembly, unless you can find one from an e-Pay radio killer. Are you sure the pot us bad, or perhaps just dirty? Or maybe dirty/oxidized Molex pins on the 2nd IF/AF board.

Google can find you the service manual.

RF pot 10K linear taper AF pot 3K audio logarithmic taper
Weird that the RF pot is worn out, usually the audio goes first.

I think the pots are CTS. I've bought CTS pots from Antique Electronic
Supply (Tubes and Such) and taken them apart to get the element.

3300. T-4XC carrier balance

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-02-19 13:29:00 UTC
From: Steve
Topic: 3300 Message: 3300

Hi - can anyone tell me the implications of an incorrect carrier balance setting? My T-4XC puts out about 130W on 20M on tune, about 350 mA plate current. All seems ok, but I get weak reports on 20m (and higher frequencies) - weaker than with my FT-847 at 100W. In general, if I'm receiving a station below about S5, he will not hear my call on the T-4XC, but will with the Yaesu.(I generally receive reciprocal reports with the Yaesu).

I'm using the Shure 444 mic, all seems ok, except when I check for carrier balance on a nearby receiver, I do get an S9 carrier coming through about 1.5 kHz above the tx frequency when on LSB - this with the tx gain control turned fully CCW.

The audio sounds ok on a remote rx.I have checked for splatter and spurious transmissions, both seem ok, but I am just using another rx in the shack for this. I would say the splatter is wider than on my FT-847, but no more than a couple of kcs and that's with a receiver right here on the bench with the tx.

When the mic is keyed in the above test (LSB, gain fully CCW), there is negligible output power. (I can see no deflection on the 20W scale on my old FC-102 ATU power meter).

I'm using an AADE digital frequency display and this works well, showing exactly 5465 kcs when the preselector is off-tuned (using both rx and tx PTO controls). On the higher frequencies, the digital display loses the signal when transmitting SSB, with the digits changing apparently randomly. It stays stable in 'tune'.

The poor signal reports happen when I operate in the 'separate' mode as well as in the transceive modes.

I'm reluctant to open up and start making adjustments unless I'm sure I have to, hi. If anyone has had a similar experience or can advise on the apparent poor reports, or the question of carrier balance, it would be very helpful.

Thanks and 73,

Steve MW0KST

3301. Re: T-4XC carrier balance

Hi Steve:

Well..the implication is that energy that should be going into your voice component of the siganl is not..instead it is being sent as carrier.

The carrier balance adjustment is easily upset by vibration or moving the rig around over time so I find I have to do it a couple of times a season.

I do it by listening on a monitor rx like you are doing. (Dummy load) and you don't need to load up to much power. Turn the mic switch off or mic gain all the way down. I use headphones and adjust the car adj pot and its trimmer cap alternately for the least carrier signal. It is a fine adjustment and once you get close, is very touchy. Alternative is to do it using a dummy load with a scope or voltmeter on the output.

I use the AADE digital readout on my A and B versions also. Works ALMOST...on Above 20M it is iffy..suspect it needs a little more signal. I have a small amp to install from idiom press I think that might help.

Mine also does the random digitts when in transmit..I think it is RF getting to the display unit tho..try bypassing any power leads and a ferrite bead on the rf cable.

Hi Curt,

Thanks for this - ok, if I should be getting almost zero carrier in SSB transmit with the tx gain turned fully CCW, it needs attention. On 80m, my signal reports are good, but hard to tell as when the band is open, nearly all signals are 59+, hi.

Am I right in thinking the carrier balance is not frequency sensitive? I.e. once set for say 20m, it will be good for the other bands too?

Tks also for the comments re the AADE display - good to see I'm not alone in this. I had thought of making up new inj cables, or adjusting the inj trimmers. Again, my C-Line is way to nice for me to be tinkering with its insides without proper 'instructions'!

Much appreciated,

73, Steve

You are correct on the frequency sensitivity..band has no relation to the carrier ballance. The carrier balance happens prior to the sideband/bandpass filters and so it is prior to the final mixing up to tx freq. The 5645 osc feeds the balanced modulator along with the audio.

Also, it makes no difference where the mic gain is set either. Only reason to reduce it to zero is to keep any stray audio from making the balance adjustment difficult.

Tweaking of the injection trimmers can help the higher freq response of the AADE display but it doesn't seem to make any difference in the tx scramble issue--which I really blame on RF.

I Made up a special injection cable y..tried many different set-ups but anything that allowed the rigs to work as they should made no difference in the proper operation of the AADE unit.

BTW..the proper car balance is way too sensitve to be seen except grossly by looking at the wattmeter or plate current. That just gets you close.

Joe -

Here is the schematic from my Service CD for the B-Line. If you work on your radios you may find it helpful.

Along with high quality scans of the original manuals, it includes both schematic versions for the transmitter and all four versions of the receiver, plus manuals of associated equipment such as the MN-2000, MN-4, L-4B, C-4, W-4, etc.

The main feature is the full color, high resolution photographs of the chassis and all boards with all parts identified and keyed to complete parts list.

Further details at <www.k4oah.com)

3306. Re: T-4XC carrier balance

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-02-19 19:08:38 UTC
From: Steve
Topic: 3300 Message: 3306

Thanks Curt - all understood. I just ran a test with a 'local' 40 miles away on 80m LSB - he scanned the band fully up and down while I was transmitting. Nothing spurious was heard by him, and my signal had the right bandwidth. Reports were 30 over 9 both ways with very good audio. Hm, if the carrier balance was way off, then we should have noticed it - I think...

I'll still do the carrier balance adjustment, but given the weak signal report problem is on 20m USB, I guess the next test is for LSB on 20m.

Good advice on the AADE display and cables - yes I was all set to try making up a variety of cables - including a 'Y', with gold connectors etc. I did think the digit scrambling on tx was related to weak inj signals somehow getting weaker, hi. I'll try some ferrites instead - power for the AADE comes from the back of the R-4C. The readout works well on all bands except 10m where it works only when the rx PTO is used, and then I have to get the preselector bang-on.

Thanks again,

73, Steve

Joe,
I've got the manuals for a T-4XC and R-4C in pdf format. That's about the best "quality" I can offer. Send me your offnet email address and I'll send one or both to you if that'll help you.

I strongly recommend this disc. While there are decent manuals in PDF form on the web the disc has them all in one place. In addition, the "service manual", which is not a factory manual and is not available anywhere else, is extremely valuable for trouble shooting because it has a complete list of parts with specifications and pinpoints their locations. It also has high resolution color photographs of all the chassis and circuit boards with identifiers for the components. There is also other stuff on the disc including a couple of alternate versions of the schematics and much material not included in the regular

factory instruction books.
I had both the RX and TX manuals printed out at Kinkos
for not too much and also had 18"x 14" prints made of the
schematics. The files are high enough res to make even
larger ones if desired. The large schematic are very
valuable for tracing wiring around. One can use colored
pencils to avoid confusion.
Gary's discs are not expensive and are actually cheap
considering the value of the contents.

Just another thought.

20 is the first band up from the bottom where the standard is USB. It is possible that there is a problem with the filter or the carrier oscillator centering causing the output on USB to be weaker than the LSB.

You could probably observe this by monitoring the output signal with a voltmetrer or scope while changing from Upper to lower.

Others here might better comment on this since my experience is A and B series only.

On the AADE, I would bypass the heck out of that power line coming into the display box. I have noticed the scrambling proble while the display is powered up but a different rig is running in the shack...thats what got me going on the RF problem. ie display connected ond ON but its R4B is off and I am using the TR7. the 5645 display goes crazy.

Subject: [DrakeRadio] Re: T-4XC carrier balance

I will adress the carrier balance problem. I am no
expert on Drake stuff but have had to fight some problems
with a T-4XB which has a similar ring modulator and IF
system. The carrier suppression on these transmitters is
unusually good, speced at -60db. The carrier balance is not
hard to adjust. I find it convenient to use a scope on a T
connector in the output cable while the TX is tuned up into
a dummy load. The signal frequency is irrelevant to this
adjustment.
The book method is to tune up the transmitter. Then put
it in upper sideband. Unbalance the carrier pot by turning
it all the way one way, the direction does not matter. The
TX is then keyed by shorting the center conductor of the mic
input to ground or using the PPT switch on a mic either done
with the gain all the way down. The next step is to adjust
the frequency of the carrier oscillator to get equal output
on either side band. That may take a bit of juggling. Once
you have it on frequency adjust the cores on the IF
transformers for maximum. This can be seen on the output.
Re-check the LO frequency and again adjust it for equal
carrier on the two sideband positions. Once this is done
re-adjust the carrier balance pot for minimum. The null
capacitor may also require some adjustment. The two
adjustments interact a bit so you must juggle them to get
the absolute minimum. I have to turn my scope up to nearly
maximum gain to see this, there is very little carrier
there. Using a receiver on CW to hear the residual carrier
may also work but I am concerned with leakage with the TX
and RX close to each other, but, its worth trying.
I think the balance should be pretty stable. There is a
temperature compensating cap in the circuit, across the
balance cap.
When tuned right the two filters should sound about
alike. A noticable difference in sound or signal strength
between the two sidebands may indicate that the LO is
mis-tuned. Of course, it couls also be a bad filter or
something in the switching but the LO is easy to check and
adjust and would be my first point of attack.
I am still fighting another problem with my T-4BX, the

main problem I have is limited time to work on it. Very
frustrating.

Topic: 3311 Message: 3311

Thanks for the information, with this information I was able to repair it.

I disassembled the pot, the carbon ring was cracked at one end at soldering lug, it wasn't worn out just broken .

I did have a 10k pot, so I was able to lossen the tabs, replace the carbon ring with solder lugs and reassemble with the oringnal wiper and sleeve.

It worked perfectly......removing the pot was harder than the repair itself.
Thanks again,
Ed

Hi Richard and Curt,

Thanks to you both for this - well for me, this would be quite an undertaking.

I have a sked tomorrow with a local for some USB / LSB tests on 20m, so let's see if there's a difference between the sidebands. I'll postpone opening up the T-4XC until after the test, hi.

Well, time, lack of test equipment and being new to the Drake and valve radios are my limiting factors, hi.

Thanks and 73,

Steve

From: Dale
Topic: 3314 Message: 3314

I have sold my TR-4CW/RIT R-4C and have the following items now excess:
Shield can- think this must be for the preselector- has the 6JB6 tube warning on the top.

Rear panel crystal cover in good condx

6 6JB6 tubes- unknown quality. 4 are Sylvania 2 are Phillips. 4 in boxes.

4C main tuning knob.

Inrad 6KHz A.M. filter for using the transceiver TR-4 on A.M. Comes with on board enable/disable relays and bracket to mount next to the CW filter

Make offers if interested.
Dale W4OP

Hi Kris,

Here are some articles:

http://www.wb4hfn.com/DRAKE/DrakeArticles/TR4_AM-Filter/TR4CW_AM-Filter_01.htm

http://www.wb4hfn.com/DRAKE/DrakeArticles/TechTips/TR4C-AM-Filter.htm

My version did not use the CW filter position- but rather, enabled the AM filter by replacing the RIT pot with one that had a switch on it. When pulled out, the AM filter was enabled (also easier for casual tuning around on CW mode). The user was alerted to the fact that the AM filter was enabled because one of the onboard relays was used to illuminate BOTH USB and LSB. I have many pix of this mod if interested- only applicable to the TR-4CW/RIT for my mod.

Here's a pix of the board/ filter and bracket.

3319. "C" Line issues

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-02-22 01:18:31 UTC
From: w3rxo
Topic: 3319 Message: 3319

I recently purchased a near mint condition "C" Line from a fellow, and was told it had just been gone through and aligned by a fellow who works on them for HRO, San Diego. It has a Sherwood mod switch in the back, and some paperwork for the stuff Sherwood did to it.
Well, I made my connections, grounded it well, and plugged in the antenna. I turned it on and got it warmed up. When I went to tune her up, I put it in the separate, and then brought the two vfo's to similar positions on the same band (75M). When I turned up the volume, I got a signal similar to that heard, when my "B" Line is in the spot position (bird chirping). I double checked that all switches are in the righ position, and that all interconnects are connected to the corresponding receptacle, at each end. Everything looks good. So, I turned the switch to spot and the signal went away. So I tried the transceive switch in the receiver position, and the bird was back. Tried it in the transmitter position, and same bird. It seems that the only time it is NOT giving a spot signal, is when it is in the spot position.
Does anyone have any clues what I have done wrong? I tuned it up, as though it were my "B"Line, and it is tuning to about 125-130 watts, about what I would expect. But I get the bird whenever the radios are tuned together, and the receive is not very good. I didn't pay top dollar for them, but I didn't get them at a price as though they were fixer-uppers, and I'd hate to have to ship them back to Jeff Covelli, just to get them right.
I am hoping I have given enough information here, to have someone recognize the problem, and point me in the direction of the solution.
Thank you in advance for the help.

3320. Access to the TR7 meter

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-02-22 19:11:52 UTC
From: w3crr
Topic: 3320 Message: 3320

I am one step away from finishing the restoration of my second TR7 (so I'll have a spare). I need to mechanically "zero' the rig's power meter. To do that, it would appear, I must remove the meter to gain access to the adjustment screw on the front.

What's the best way to do this? I don't know about you, but I have been known to disassemble an entire piece of equipment in order to gain access to one component, only to learn later that I could have accomplished the same thing by undoing two screws.

Thanks and 73,

Craig

As I recall, it's not terribly difficult. I think that I had to drop the front panel - remove the band shaft knob and the two screws on the rear detent mech so you can pull the band shaft out from the rear just enough to clear the front panel. Then, remove the top two screws on each side that secure the front, and loosen the bottom screw slightly. The DR-7 board will need to be pulled to allow room for the PTO to swing up as you hinge the front panel down, but this should be easier once you tip the panel forward a little. After that, it's just a couple of screws and an aluminum bracket, and the meter is loose. Make sure the meter is lined up straight before you put everything back together.

It's not as complicated as it sounds. :) There may be an easier way, its been a year or more since I've done it and I'm going by memory here. It might be a good idea to wipe the meter case down with some sort of anti-stat solution while you have it out. There are commercial products available, and I have also seen "recipes" on the web for home-brew (no still required).

I just became the proud owner of a TR5. I am thrilled. In comparing it to my TR7 it seems quieter. Only did preliminary comparison but seems to be hearing as well. Does anybody know how the RX in the TR5 stacks up to the TR7? Somebody once said that best thing one can do for the TR7 is to use an external power switch cuz there is no replacement for the AF/RF switch in the TR7. Does the same hold true for the TR5? Any other tips for the TR5? Tnx. 73/Crit/K4BXN

Crit -

Congratulations! I've never owned a TR-5, but I believe the big advantage over the TR-7 is the synthesized "PTO", making it much more frequency stable.

I'll be interested to hear what you think of it.

The external power switch is a good idea for just about ANY piece of equipment. Even if the part is available, consider whether you would rather replace a standard toggle switch in a simple box or panel, - OR - a special switch buried three layers deep inside a piece of equipment! It's an easy decision for something like the TR-7 where there is just no equivalent component available. It's even getting hard to find a "standard" 500k audio tape pot with an SPST switch on the back, which was used in just about every receiver or radio for 70 years!!

Depends on if you get caught or not... hihi

Used to love it when the guys at work would win the (Nevada) lottery and get a deer tag! I used to tell them just go to Tongass Hardware in Ketchikan, Alaska. Non resident deer tag was (either) $35.00 or $50.00 (forget which now)..... LIMIT 6 DEER!!

Hi Garey..

CD came today. Thanks for the quick delivery. Now my original manuals can stay in the large ZipLock baggie and I can print out the working manuals.

Now have to find someplace to buy a complete set of tubes..to have as backup. Going to borrow a friend's tube tester and test all the tubes...I suspect there are a few bad ones in the receiver as only one shows any filament glow or warms up. Haven't fired up the transmitter yet....want to bring it up on a variac...been 10 years since the radio has been on.

I want to tear it apart and get it on the air as soon as possible, but I really should put the FL2100B back together first....then that legacy station set can be put on display.

(It only took 36 years to get my B-Line....I know....I was in a rush....always in a hurry.)

Thanks again!

You can check filaments with an ohm meter. That will at
least tell you if the non-lighting tubes have open
filaments. I suspect not, bad filaments are actually pretty
rare. I strongly suggest checking socket resistance and if

you don't find anything way off there measure the socket voltages. Tubes can be removed for the resistance measurements but not for voltage measurements. If you can come up with a set of socket extenders they will be a big help. Most of the voltages can be measured under the chassis but be very careful especially in the transmitter because of the high voltages.
I also got the disc a while back. I have printed out the instruction manuals and Gary's manual with the photographs in it. I also had extra-large prints made of the schematics. The last are a big help because they make it easier to trace wiring around. A set of colored pencils will also help.
I strongly recommend this disc to anyone who has the equipment even if it all works perfectly and you never intend to work on it. There is a lot of information there that you will not find anywhere else.
Its cheap enough to get the manuals printed and bound at someplace like Kinko's plus they will print the large schematics for a couple of dollars each. The schematics on the disc are very high resolution and can probably be printed billboard size.

3337. TR7 PIN DIODES

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-03-04 18:17:47 UTC
From: w1fued@sbcglobal.net
Topic: 3337 Message: 3337

Hi All,

I am trying to get my first (broken) TR7 running. The rx is up and running, but no output on TX., when keyed on cw, there is kinda of a chirp when going back to rx. Very little power out, about 1 w. , and digital dial shifts approx 200 hz between tx and rx

In testing the 3 pin diodes on the high pass filter board one appears to be bad according to the testing process (on the tx side). I will order some replacements from Down East....

My question is about the pin diodes in the forward board, they have been replaced with fast switching diodes (1n4148. They show no voltage when the calibrator is off, and 4.6v or so across them when calibrator is on, maybe this ok, I dont know.

Are the 4148 switching diodes ok for replacing the original MPM 3404 diode, or may this be an additional source of my problem?

Help would be appreciated.
Thanks,
Ed

Al -

I don't have that combination, but check the PIN diodes that switch the filters in and out.

Also check the "-5V" supply (typical voltage around -3.5V) on the Power Supply board. The filter switches are the only place this is used, and is used to reverse bias the diodes that switch the filters in and out. There is a series and shunt diode at each end of each filter.

Thanks, Garey

I've gone through the PIN diodes - they seem fine, as do the supply voltages. I've even gone to the extent of replacing the associated components with surface mount parts with the hope that I'd reduce stray coupling.

When I'm about 3 kHz above or below a strong signal of -70 dBm or more, I end up with high frequency energy (~3 kHz) from that signal in my passband. It's not very strong, but enough to cover up weak stations.

I was just wondering if anyone has experienced anything like this before I invent a fix. I was thinking about trying different PIN diodes and modifying the switch circuit to use the 24V supply rail for reverse bias.

Al -

OK. Well the -3V is plenty to turn off the Series PINs, and plenty to saturate the Shunt PINs. Signal voltages are millivolts or less, so higher reverse bias won't help.

I'd look at grounding of the board and connecting the top and bottom ground planes together. I'm not certain, but I believe Drake specified 100 dB ultimate rejection for the IF.

Also look at the decoupling electrolytic caps involved..

Ed -

The 1N4148 diodes will 'sorta' work, but are probably not the cause of your other problems. If they SHORT, they'll knock down both receive and transmit levels considerably, but not to the extent you are describing. These diodes are used to switch the calibrator signal into the receiver. They are not back-biased to ensure they are OFF, and the PIN diodes will give considerably less coupling in this condition than the 4148s. When the calibrator is turned ON, the two diodes are in series, forward biased between two 1k resistors. So you should read about 5 volts on the cathode of one diode, 5.6 volts 'between' the two diodes, and 6.2 volts on the anode of the "top" diode with the CAL on. If the voltage is the same on either "end" as the "between" voltage, that diode is shorted. You can just remove them for the time being, the only loss is the calibrator function.

Replacement MPN 3404 diodes are available from <www.kitsandparts.com>, six (6) for $3.00.

First off, are your +10T and +10R voltages switching properly?

>Are the 4148 switching diodes ok for replacing the original MPM 3404 diode, or may this be an additional source of my problem?

I would say no, 4148s are probably not OK. I'm sure they probably tried it at
some point and found them lacking.

Thanks Garey,

Well when I visited the Downeast website, I saw they had the mpn 3404 pin diodes for 25 cents apiece, so I ordered 4.

Those two diodes dont look that hard to get at, but the other 3 will be a challenge to get the iron in at the angle required. I hope the diodes are the problem, though I dont think so....gonna try to see if I have rf from the exciter.

Joe -

17M yes, 60M No. The IF of the T-4XB is 5.645 MHz, the PTO covers 5.455 - 4.955, too many bad mixing products. Aside from that, I don't believe the B-Line meets the stability requirements of 60M. You could certainly LISTEN to 60M, there's a chance that one of the rogue mixing products is NOT right on a channel you want to listen to, but transmit?? No.....

Hi Jim,
Thanks for the hint......
The 10 volt line was not switching......turned out the pnp switching transistor was bad on exciter board, q307, I think it was...
all I had here was a 2n4125 to put in....but that did the trick. Removing (replacing) the display board was a bit challenging.
130-140 watss out- 100 at 10 meters, just as the book says.
After adjusting the s meter, still only s8 at 10 meters on rx...hope its the pin diode.

Will change out the 2n4148 when I get the pin diodes from Downeast..
#9968 alive again..

Thanks,
Ed

3350. FS TR-7+ Power Supply RV 7 and MS7

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-03-05 04:53:49 UTC
From: n5dpk
Topic: 3350 Message: 3350

TR7 is serial 5252. Has all the filters. Power supply and radio has cooling fan. Has the Noise Blanker also. 150 watts output. General coverage receive and transmit has the MARS mod. Works 100 percent. I also have the RV7 remote VFO and MS 7 Speaker. Come with the matching Drake desk mic. Asking 900.00 and split the shipping. Pick up in East TX

Dennis n5dpk@yahoo.com

My next course of action will be to pull the filter and bring it into work next week so I can run a sweep.

I want to exonerate that before trudging ahead.

I could always insert a 1 KHz LPF into the audio line to get rid of the undesired products, but knowing it's still there would keep me wondering what else is showing up in the passband that shouldn't be there, or it it's hitting the AGC.

So...Essentially the FS-4 is an unneeded toy. I would be better off to just spend the money for a set of 17 meter crystals.

Hmmmm.....

Joe -

Yeah, if all you want is 17M, the crystal(s) are a much better idea!
29.1 MHz from any of several reliable suppliers.

International Crystal Mfrs

<http://www.icmfg.com/>

Not always the cheapest, but quality crystals that work. Just tell them
what you want it for and they know the rest.

You might also try

<http://www.mhelectronics.com/>

They no longer make custom crystals, but have a good stock of "standard"
crystals at good prices.

From: Ken Simpson, W8EK
Topic: 3355 Message: 3355

Drake items for sale:

Drake TV-3300-LP Low Pass Filter
This is a modern low pass filter to go between your transmitter and antenna, and has been optimized to have more attenuation in the 40 MHz region, where many TVs have their IF. It is good for 1000 Watts "average" according to the manual, and has over 80 db attenuation at 41 MHz. This one looks great, and includes the paper work. $30

Drake TV-5200-LP
This is the more modern version of the Drake TV-1000 Low Pass Filter. This is the filter that may also be used on the low end of six meters, as well as HF. It is good for 1000 Watts average below 30 MHz, and about 200 W up to 52 MHz. It works fine, and is in very nice shape. $35

Case for Drake TR-33 C
This is the black case that fits the Drake TR-33 C, and has cutouts in the back for antenna, power, etc. It includes the shoulder strap, and is in good shape. $12

Case for Drake TR-22
As above, but for the TR-22. No shoulder strap. $10

3 pin mic plug for TR-22
This is the small 3 pin mic plug that fits the Drake TR-22 mic jack. It is much smaller than most of the mic connectors. I thought these were completely gone, but one appeared from a silent key. This one has been used, but should still be usable some more. $10

Communications Speaker
This 4 inch square speaker is optimized for communications frequencies (300 to 3000 Hz). It is in a black enclosure, and is an 8 ohm speaker. It has a cord with a 1/8 inch (3.5 mm) mono plug on the end.
This one works fine and looks OK also. $15

Microphones:

All of these microphones have been tested and work well.

Shure 401 B, Low Z Hand Microphone
This mic has characteristics similar the the Shure 444 Desk Mic, but this one is a hand mic. It is a controlled magnetic mic, with frequency response tailored for voice

communications. It has a rugged case, and a heavy duty coiled cord. 4 pin connector. With paper work for $40.

Shure 104 C, Low Z hand Microphone
This is a very heavy duty Shure mic. It appears to be new, with stripped and tinned ends that have never been on a connector. It is in its original box, with the original instruction manual. $30

Chrome Low Z Hand Microphone
This mic is chrome plated. My memory says it may have come from a Polycom rig. The mic is a good solid metal case with chrome plating all around, with a black PTT switch and black coiled cord. There are some pits on the chrome; it works fine. $30

Generic Hand Microphone
This is a low impedance hand microphone, black in color.
With 4 pin connector. $25
With no connector. $22

Lafayette EAM-15 dynamic hand microphone
2000 ohm impedance can be used any place a dynamic mic is needed. Stripped and tinned leads.
It works fine, and looks good also. $25

Generic Hi Z Hand Microphone
This hand mic is black in color, and looks like it might have come from a HyGain rig. It has a PTT switch and black coiled cord. $25

DTMF Touch Tone Microphones:

KDK DM TT-1 DTMF Touch Tone Microphone
This mic has a 12 digit touch tone pad on it, along with a switch to turn the pad on and off. I presently has a 4 pin plug on it, and can be used on most any rig. It works fine, and looks great. $35

CES 655 L "Microdialer" DTMF Microphone
You can manual dial a number, or automatically have it stored in the mic, and "speed dial" with this mic. 12 digit touch tone pad on the front, with the microphone part above the pad. This one presently has a 4 pin plug on it, but of course that can be changed. $35

CES 600 L, Universal DTMF microphone
This has a normal touch tone pad on the front, with a low impedance microphone. This one has the 8 pin modular plug (like a computer LAN) on it. This mic has not been used, so it is in really great condition.
With paper work for $40.

Data Signal "Data-Coder 5" touch tone mic
This mic has a 12 digit touchtone pad on it, plus a
normal low impedance microphone. With 4 pin plug.
Like new. $38

Speaker Microphones:

MFJ-287 Speaker Microphone
This was used on a Kenwood TH-225 HT, but it also fits
the TH-21/31/41 series HTs, TH-215, TH-415, as well as
others. It has a 3 conductor 3.5 mm plug and a 2 conductor
2.5 mm plug. $15

Kenwood SMC-24 speaker microphone
Fits Kenwood TR-2400 HT and others. This one looks fine
and works fine. $18

Azden SDX-316
This is the rounder style speaker mic that fits nicely in
the palm of your hand. Has 3.5 mm and 2.5 mm plugs for
Azden, Icom, some Yaesu, and others. $ 20

Cable for straight key
About 3 feet long, with a mono 1/4 inch phone plug on it,
as is used with a straight key. $5
As above, but 1/8 inch (3.5 mm) plug. $5

Cable for paddles
About 3 feet long, and with a 1/4 inch stereo connector
on the end, like used by most rigs. $8
As above, but 1/8 inch (3.5 mm) plug $8

Coax Cable with Type "N" Connectors:
This cable is made of RG-8 coax and is about 6 feet long.
It has a male type "N" connector on each end. $15

Coax connectors and adapters:
Prices are per connector. Several of each are available.
These are NOS (have not been used).

BNC male for coax cable
standard type - $2
crimp on type - $3

Chassis mount BNC female
square mount (uses 4 screws) - $3
screw in type - $4

BNC 90 degree - female to male - $3

BNC "T" - two female and one male - $4

Antenna adapter to fit the BNC connector on the HT
and provide an SO-239 connector that will permit

a PL-259 to be attached. (BNC male to UHF female) $5

UHF Male (PL-259) to BNC female (opposite of above) $5

UHF double female "Barrel connector" (two SO-239 together) $3

UHF "T" connector with two female (SO-239) and one male
(PL-259) connection - $5

Prices do not include shipping from Florida.

Thanks.

3357. Sidetone in CW

Yahoo group: DrakeRadio (2006 — 2011)

Topic: 3357 Message: 3357

I finally finished going through my T-4X in preparation for putting it on the air. I rebuilt the power supply, and replaced the final cathode and screen resistors as well as the meter shunt resistor. It is connected to a R-4A per the T-4X manual. The funny thing is, that when I switch the Function switch to X-CW, a tone is produced in the speaker even if the receiver is off! This is with no key plugged in and the mic either plugged in or not. The only way to silence the tone is to unplug one end of the Anti-VOX cable. Is this normal? Other than this quirk, the rig seems to tune up fine in SSB, except for carrier balance, but that question will be addressed on another thread. Any suggestions would be appreciated, either on or off the list.

Randy -

Yup, that's normal. We just went through this somewhere.... :-)

The KEY jack is a "shorting" type, closed when nothing plugged in. Even with the a key plugged in and "open" the KEY lead is shorted with a contact on the TRANSCEIVE switch when it's in the SPOT position to enable the IF and Driver stages. The sidetone is fed through the ANTI-VOX cable to the receiver where it is applied to the primary of the AF OUTPUT transformer. So the receiver does NOT have to be on!

In the T-4XB, the cathode of the ANTI-VOX amplifier is lifted in SPOT to mute the sidetone. Just the way it is (was)! :-)

3359. Keeping them cool

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-03-09 03:54:58 UTC
From: John
Topic: 3359 Message: 3359

Hi All

I have an excellent Drake R-4A and have done the necessary maintenance to keep the as good as new.
I did buy a really nice R-4C that was loaded, but I went back to my R-4A as it was just better.
I found it nicer to tune, the PTO gearing is so smooth, the noise blanker is the best I have every experienced, far superior to the R-4C and all the controls just make sense.
It turned out not to be a hard choice at all.

I have done a few mods, this one is probably the most important.
Valve receivers for me, are great, I do have a few nice modern receivers but the when the signal are very low and the noise is high the R-4A is the only one that can pull them in.

I use it sparingly as it does get HOT, the transformer is usually about 65 Deg Celsius.
Most of the parts are original, few have been replaced. the main filter cap is impossible to find, so I needed to decrease the heat load on it.

I came up with the simple heat shield.
The transformer still gets hot but the Cap and PTO do not.
I placed some images in the photos area for you to use.

Before the Mod, PTO and Cap were at 65 deg, Celsius
With the shield, PTO and Cap is about 8 Deg above ambient, about 28 Deg C.

This is a heat shield made from scrap corrugated cardboard.
The corrugation holes go for the bottom to the top so a small amount of cooling air helps to keep the cardboard cool.
a few small pieces of double sided foam tape holes the shield off the PTO and the cap.
The shield is about 3mm from the copper surface.
I selected white as the face to the valves as white reflects heat.
The effect is over 40 degrees celsius cooler for both the PTO and the main Cap.
Heating a cap is the best way to dry it out, thus shortening its operational life and the PTO is effected by the heat from the surrounding HOT valves.
A hole was made in the shield to allow the PTO slug free movement

I hope this mod is useful to someone else.

Regards John

John -

Cooler is always better! There were four different versions of the
R-4A, what is the serial number of yours? The first two versions have a
tube (valve) Product Detector, the last two have a diode bridge PD.

The main filter cap is, or will soon be, available from

<www.hayseedhamfest.com>

Tom makes very nice replacements for all the Drake receiver in the
Twist-Lok package.

Your heatshield is a very "cool" idea! :-)

Hi Garey

My R-4A is the 13 valve unit. Serial number 2914

It has the valve Product Detector.

The best detector I have heard, is in the Drake 2B, it is even better than the R-4A.
I just find the 2B a pain to use due to its unique sliding scale, backwards or forwards now which frequency am I on, way to hard for me. But the 2B has a lovely audio and is a very nice receiver.

Thank you about the link to get a replacement cap, as mine is probably a little lower than when it was new.
I am getting a little humm through, I can only hear it when I have headphones on.

Regards John

I don't know how they compare, but I do really like the sound of my 2-A. I don't listen to it as much as I should....

3365. T4XC transmit problem

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-03-13 10:59:18 UTC
From: martin.benoit@sympatico.ca
Topic: 3365 Message: 3365

Hello to all

Few weeks ago i got a R4C and a T4XC with very dirty switch.
I clean switches. It came alive.
Now ... i hope ... there is only one problem.
On 15 meters
mode switch on tune output 125 watts. Put the switch on CW and NO output.
On other band it is OK.
Any idea ?
Tnx
Martin

Martin -

This is a very strange problem. Are you increasing the GAIN control on CW? It is sometimes necessary to increase the GAIN control to almost maximum on CW on the higher bands.

The only difference between CW and TUNE operation is the way the signal is generated, and this is identical on ALL bands. If TUNE works, then all the amplifier chain is working normally.

In TUNE mode, the MIC Amp is converted to an audio oscillator and the audio tone generated is applied to the MIC input, (same as whistling into the microphone,) which goes to the balanced modulator and through the rest of the amplifier chain.

In CW mode, a DC bias is applied to the balanced modulator to unbalance it and allow the carrier oscillator to come through. This signal is shifted in frequency from its SSB position between the two filter passbands, to within the LSB filter passband so it can go through and on through the rest of the amplifier chain.

Both of these modes are accomplished in exactly the same way on all bands.

I was wondering if any has ever modified a heathkit p/s for use on a drake tr-4. Just pick one up at a local hamfest w/o a power supply. I have a heathkit p/s modified for a swan 175. 73 Bob kb3pet

3369. 2A Calibrator

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-03-15 14:15:10 UTC
From: wa4zzw
Topic: 3369 Message: 3369

Did anyone but Drake make a calibrator for the 2A, 2B or 2C?
I bought one at a hamfest that plugs into my 2A with proper connectors but does not look like one made by Drake. It is not the copper color and is a bit taller. It came without a tube and I assumed it would use the same tube. I plugged it in and the filament lit up but it did not work. I will check the tube and crystal but just wondering if anyone knows what I might have. I don't think it's homebrew as it has part numbers and inspection markings.

Topic: 3370 Message: 3370

Hi All

I would like to power my R-4A from a car battery.
I have done this with my Eddystone and the noise floor is silence, at full RF and AF with no antenna there is just NO noise.

I would now like to do this to my R-4A, it would be an incredible receiver if the same thing was possible.

Did Drake provide a DC power supply for the R-4A?

If it did, what is its part number?

Does anyone have one they would like to sell?

If there is no such device, I think I will be making one, I just got to try it.

Thanks in advance.

John,

Drake built a DC-4 although I it was designed for the TR4 series, nothing specifically designed for the R-4c that I know of. An inverter (12vdc to 120vac) may be a better/cheaper option.

If you need a DC-4 I think I have one, contact me off line at mikestahoe at yahoo dot com.

HI All

I do understand, I will have to do a mod to the power supply, like completely disconnect it, I will leave the parts in place, but it will need to be disconnected just for safety. Or maybe I could use a few diodes to block the supplies from each other.

Just had a look into the R-4A schematic and it does not look too hard.
I need 160VDC at about 70mA
The heater supply is 12.6 VDC at 2.4A, car battery voltage.
I will need to place in parallel a 42ohm resistor with the v7 heater.
So the total is v2,8,6 in series with v7 and the resistor will work off the 12.6v battery.

I don't think I have missed anything.

What do you think, is it possible?

Thanks for looking in.

/<quote>
VDC ?

Now its a long time since I did my old valve theory, so I cant remember the reason for running valves
with AC instead of DC on the heaters but there is a reason.....

Which actually makes me wonder whether you have tried a "low frequency" inverter to test for noise ?
eg: http://www.jaycar.com.au/productView.asp?ID=MI5180&CATID=8&form=CAT&SUBCATID=680
Actually I wonder how noisy one of these inverters are to start with ?

HI Gary

You are very right there was a reason why AC was used for the heater.
Thanks for the reminder, I studied this a long time ago.
A DC powered heater get very hot in a small section of the heater element instead of over a larger section of the heater element. DC can reduce the life span of a heater by hundreds if not thousands of hours.
I will not be using a separate DC supply.

The Jaycar low frequency inverter is not in the store where I live, unless I buy it, so testing it is not possible.

I just read from Garey - K4OAH, that the DC-4 outputs 115Vac @1.3A.
So I think I will be getting a DC-4 to try out.

Does anyone here got a working DC-4?

Bob,

The model 2AC was the matching plug-in calibrator for all of the 2-line receivers. They're scarce and "spendy" these days, but you can occasionally find them on eBay.

My current 2B came with a homebuilt calibrator that plugs into the normal socket. It doesn't look anything like the "real thing", but it works just fine. I've built them myself in the past (I've owned many 2B's over the years!).

Your calibrator may have been adapted from some other rig, since it appears to be factory made. To see what you have, take the calibrator apart and draw out a schematic, then compare that to the Drake schematic (it's in your receiver's manual).

Since you got no output, the crystal may be bad, or you may be using the wrong tube. If you have a 100 KHz calibrator in some other rig, or perhaps one of your friends has one, you can use it to test your crystal. There's no guarantee the crystal will work in a potentially different circuit, but the chances are reasonably good.

Worst case: disassemble and rebuild your calibrator to match the Drake schematic, and use the correct tube (6BZ6).

From: dean_k5dh
Topic: 3379 Message: 3379

Hi gang,

I bought a 2B receiver at a hamfest this past weekend. I didn't need one, but I couldn't resist it for $120. It works very well, but it ain't the prettiest mare at the horse show. The cabinet will need to be stripped and painted. The chassis is covered with a haze of rust that will not clean up. The set has been subjected to some very poor quality repairs and a few minor modifications, all of which I intend to correct. The audio output transformer has been replaced with a generic part that is much larger than the original and is just cobbled into the chassis; it works, but it sure is ugly! Three of the skirted knobs are cracked.

So, to get to the point, I am in need of an original audio output transformer and three original knobs. If you have any or all of these parts available, please contact me and let's make a deal. If you intend to try to cover your kids' college tuition by selling me these parts, don't contact me. (hi!)

By the way, I have a clean, working 2A/2B S-meter in my parts stash that I would be willing to trade even-up for what I need.

73,
Dean K5DH

Thanks for the reminder John....
(
I think I have started to suffer from craft disease - Cant remember a f**king thing.
Mind you its around 35+ years since I studied valves.
)

I do have a DC-4 but not the cables :-(

From the circuit its just an inverter supply running 330Hz SQUARE WAVE.
The 110 VAC is only rated if the other outputs are NOT used.

I always run my computer systems on UPS, so I intend to do the same for my
home ham station, I obtained the DC-4 to reduce inverter load, just have to sort out
cables.

73
Gary

Subject: [DrakeRadio] Re: Drake R-4A powered by Car battery

HI Gary

You are very right there was a reason why AC was used for the heater.
Thanks for the reminder, I studied this a long time ago.
A DC powered heater get very hot in a small section of the heater element instead of over a larger section of the heater element. DC can reduce the life span of a heater by hundreds if not thousands of hours.
I will not be using a separate DC supply.

The Jaycar low frequency inverter is not in the store where I live, unless I buy it, so testing it is not possible.

I just read from Garey - K4OAH, that the DC-4 outputs 115Vac @1.3A.
So I think I will be getting a DC-4 to try out.

Does anyone here got a working DC-4?

Regards John

Dean, sorry but have no spare parts for you but I will recommend that you look up Hayseed parts on the net as they have a really bitchen replacement for the PS filters -it's beautiful, sparkles and scintillates and costs about $30 - I put one in my 2B along with their supplied audio tube cathode bypass cap and it works now better than ever before.

Good luck with the parts hunt

If you find a way to restore the copper finish on the chassis please let me know

what a great little radio the 2B is

From: Garey Barrell
Topic: 3382 Message: 3382

I took a flyer today and sent an email to "RADIODAZE", the maker of repro dials for "antique" radios, to see if they would be interested in making them.

I just got back an enthusiastic reply that they would "love to make these" if they could get good artwork to work from.!

I have a B-Series that I can get loose, (25 kHz marks,) so I'll see what happens.

This has been a problem for quite a while, and I think would be welcomed by many with darkened, scratched or broken dials.

Dean
The 2B is possibly one of the finest engineered radios of our time

#1 That corrosion on the chassis---it doesn't come off.
The steel chassis was copper plated and then protected with a clear lacquer finish.
In time the lacquer dteriorated and the corrosion developed in thin spots in the plating. After years of trying things that don't work I came up with :
Wash with mild soap and water, rinse and dry.
Then just use Meguires paste auto polish. Do a small area meticulously with a fine toothbrush and Q tips, polish, do over, polish some more and move on.
The Meguires has ammonia and cleans through the lacquer with out removing it. It will make the bad look not so bad. It wont fix it but it will improve it drastically. And, it will keep it from progressing.
Once you start being agressive and the lacquer goes you can very shiny copper that will look like crap and the lettering will go too.

#2 You can easily re-can that lytic in a couple half hour stints for a couple of dollars. It is easy to do a pro job that can't be detected.

Good luck on the project
2B are really incredible radios

Hey Dean,

You may be in luck. Was looking thru some archives here and stumbled
across this:

For Sale: Drake 2B NOS Power transformer

Subject line says it all- bought this when Drake was selling off their
older
parts.
$50 shipped.

Dale W4OP

This was sent on Feb 20. He may still have it. His e-mail addy was not
readable but maybe someone here can help there....moderator?

God bless

Hi Paul,

I agree that the 2B is a wonderful piece of engineering. So much performance from such a simple receiver! Straightforward design, easy to operate, good sensitivity and selectivity, surprising stability... does it get any better than that? Not for the price.

The top surface of my 2B's chassis is badly rusted, and there's no hope for it. There's virtually no copper plating left. The entire top surface is either rusted or has "black spot". I'll do my best to clean it up a bit. Underneath, the chassis shines like new (as if that really matters?).

I do intend to rebuild the filter cap. I just need to get to the local parts emporium and pick up some suitable caps. I'll try to get down there on Saturday morning.

Still looking for an AUDIO transformer (my power transformer's fine) and three skirted knobs. If I can't find some knobs, I'm going to temporarily replace all of them with 4-line knobs from my parts stash.

3388. Drake T-4XB low mic gain

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-03-22 13:26:14 UTC
From: w4mjr
Topic: 3388 Message: 3388

I have just bought a nice looking set of Drake 4 B Twins. After giving a good cleaning on all switches and contacts I now have them on the air and had good reports with them on CW. I've noticed a low mic gain on the T-4XB though. I'm using a Shure 444 that I have on my Drake TR-4cW/RIT. I know the finals are good. Voice peaks only about 40 watts using a Mirage MP-1 on the T-4XB compared to 120 watt peaks of the TR-4cW. The transmitter tunes fine with 100 watts input pwr. Is this normal for the voice peaks to be this low ? Bye the way the R-4B receiver is a pleasure to listen too.
Thanks,
Mike W4MJR

I also have exactly this problem. I've changed tubes
and checked for bad caps, etc. At first the problem was
intermittant. A curious thing is that gain is more than
adequate for AM. I am going to try some things later today
and will report if I am sucessful in finding the problem.

I am not sure how much power should show up in tune. I
can measure the voltage at the modulator if that helps. I
can get up to about 80 watts out, much less than in CW but I
thought that was delibrately limited by the ALC. The
waveform at the modulator is a sine wave until I turn the
gain up past the point where the power no longer goes up,
then it begins to flat top a little. I think the ALC should
not affect this point, its later in the chain. I tried
bridging C135, it didn't seem to make any difference but I
plan on replacing it later since it couples the audio, both
tune oscillator and mic audio to the modulator. It just
seems suspicious but, of course, there could be something
else also. I also want to replace the coupling caps earlier
in the circuit but those should affect the gain for AM too,
I think. I may be missing something obvious, wouldn't be the
first time.

Richard -

You should see about 120 - 130 Watts output in TUNE, flattening out by ALC, depending upon the condition of the Final tubes, power supply, etc.

C135 is _definitely_ a suspect. Leakage would apply "some" DC voltage to the BM, not good. Bridging it of course would make no difference in the leakage.

Garey here is my reading in tune mode :
100 watts input = .28 plate meter reading on T-4XB
Bias set on AC-4 like manual reads = 1/4 below .1 plate

Just tried it on AM mode with 100 watts input and when I just key the mic without speaking watt meter reads 40 watts and then when I speak with long words the watt meter average goes up to about 80 watts.

3394. Copper chassis

Yahoo group: DrakeRadio (2006 — 2011)

From: R
Topic: 3394 Message: 3394

Greetings everyone,
I have a copper chassis that's in pretty sad shape. My thought was to strip all the components off of it, have it blasted and then powder coated. Any thoughts?

Thanks,
Ray

If your going to that much trouble perhaps you can find
someone to copper plate it again. I think its necessary to
copper plate before chrome plating, at least its worth
checking with someone who does that.
The whole idea of copper plating is to lower the
resistance of the chassis for RF. Skin effect tends to
concentrate the current in the surface of the conductor so
the idea here is the same as with copper-clad steel wire for
antennas, nearly all the current flows in the copper skin,
almost none in the steel core. I have no idea how much
actual difference this makes in a chassis but Drake chose to
do it and I think they were pretty cost concious. Where it
counts they used high quality components.

Mike -

What OUTPUT power are you getting in TUNE? Bias should be 1-1/2
divisions below 0.1A

AM power SHOULD only be 40W or less input with no modulation. The AM is
a controlled carrier type, meaning that the carrier power increases with
modulation.

280 mA at 650V is 180W of INPUT power, for which I would expect about
100W of OUTPUT power.

With good finals and proper alignment, you should get ~120-130W of
OUTPUT power and about 340 mA of cathode current.

From: Eric
Topic: 3398 Message: 3398

My Tr-4 has started to have a hum on transmit on SSB. So im guessing the AC-4 caps are going bad? I already ordered a kit from the Heathkit Store to rebuild the supply.

Eric -

Most likely. If you use the transceiver, don't leave it on and
unattended until you install the AC-4R kit. You're on the right track!

I measured this using a dummy antenna and a General Radio 1800A RF voltmeter. I also get approximately the same reading using a Tek scope. The meter or scope is connected to a T in the coax. In the case of the GR meter the entire thing is continuously shielded. I measured the impedance of the dummy load using a GR RF impedance bridge and its very close to 50 ohms non-reactive.
On 80 meters, at about 3.700 khz I get about 109 watts in tune going up to about 135 watts in CW. I checked it at 28,700 and get much the same power there also. These are new tubes, NOS Sylvania. I managed to get them neutralized on 10 meters. I've replaced the cathode and screen resistors on the finals. In each case one was near the right value and the other quite high. I think the high ones were on the same side. No sign of overheating on them.
I also replaced R-36. In my TX it was marked 2.7 ohms but measured 4.4 ohms. I replaced it with one of the original value. I also replaced R 26 which is marked 680 ohms but measured nearly 900. It showed no sign of overheating. I also replaced C-135 with no effect, the old one checks good but now has very short leads on it :-) In the past I replaced the meter shunt with a metal film resistor of the original value.
Before checking the power levels I set the bias adjustment (in SSB with the gain at zero and a clip lead to actuate the PTT.

I get about 4.4 V P-P RF at the center tap of the
carrier null pot.
I have also performed the complete tune up procedure
for the IF and driver stages.
BTW, I think I wrote you before about this. I reversed
the connections to the modulator transformer so that it now
matches the photo in your disc. The result is that I get a
perfect carrier null without any additional capacitive
padding although the null capacitor is near the end of its
travel on the maximum side. Evidently, this circuit is very
senstive to stray capacitance.
I broke one lead off the ceramic 2.2 pf cap which is
across it but managed to resolder it. I should really
replace this provided I can find a new one.
Now, I am not certain about the power output levels. I
think my measurements are fairly accurate but I have another
set of new tubes I can try. These are NOS General Electric
with slightly different envelopes. I can get more Sylvanias
if necessary.
I measured the power supply voltages; they seem to be
about right and not too much ripple although I have the
Heathkit Shop kit. I need to assemble and install it.
Perhaps that would bring the power up. What I think I will
do next is to replace the coupling caps in the microphone
stage. I can probably just bridge these. The odd thing is
that there is plenty of gain for AM. Of course, that comes
from a differen place. Its also possible that the cathode
load resistor has changed. That is also something I need to
get at and measure. This problem was intermittant and I did
at one point have enough gain. Also, I changed to 12AX7 to a
new one. No difference.
Another possible clue is that there appears to be ample
gain for the VOX. I did BTW find the diode in the PTT line
partly shorted, looked like about an 800 ohm resistor.
Replaced it.
One other thing. When I slipped with a meter probe and
shorted something a while ago the filiment fuse blew. I
replaced it but the entire TX seed dead even though all the
filiments lit. At some point I replaced the finals with the
original, rather weak, tubes and it came alive again. I
checked the tubes on a friends tube checker that will take
them and they simply had no emission. Something happened to
them.
Anyway, I've been fighting this thing so long now and
am so close to having it work right that I will simply not
give up. Any suggestions are very wellcome and I will follow
them up as best I can. Please excuse the long letter but I
guess I think the more clues you have the more likely it is
that I can find the solution.

Subject: Re: [DrakeRadio] Drake T-4XB low mic gain

Later, after making some more measurements. I think at least part of the problem is the power supply, lots of ripple on the 650V supply and it regulates badly. Time to install the Heathkit shop mod I think. Also, the RF level at the wiper of the null pot is much lower than I thought. The chart you sent me indicates it should be abour 4.2 volts P-P and I am getting perhaps one volt. However, the drive in Tune and CW seems to be adequate. I think perhaps the power is lower than it should be because of the power supply. Anyway, time to work on that and try trouble shooting the TX afterward. I don't remember ever having this much trouble with anything in the past. I must again recommend Garey's discs to everyone, without them I would be even more lost than I am.

Those power levels are about right for 10M, but should be higher on 80 &
40 in particular. Those resistor value variations are not all that
unexpected in carbon comp resistors after 40 years. Interesting that
all the variation is on one tube, and means the "other" tube was doing
more than its share of the work. Not good for 3rd order distortion
products OR tube life.

This too is typical. This 1/2 resistor (R36) dissipates about 300 mW AT
resonance and can easily go over 500 mW off resonance. It's often a
casualty of a "slow tuner-upper"! R26 is typically a casualty of
someone aligning the compression trimmers with a metal bladed
screwdriver. Even a momentary short to the side of those little holes

can be damaging as it puts the entire 250V LV across that little resistor. Approximately 90 Watts!! R38 is selected to set the meter reading at 70 mA for about 190 mV across R36.

That's about right. You should have ~ 1.5V p-p at the INJ jack on the back panel, and ~ 6V p-p at Pin 2 of V4, Driver grid.

Never run into that before. Makes sense though, since there are very low capacitances involved.

I don't see any problem with your power measurement technique. With a quality, calibrated scope, and an accurate load, that is probably one of the most accurate measurements we can make. The only cross-check I can think of would be to measure the cathode current with a DMM across R36 (~340 mA) and the plate voltage (~650 VDC under load) for 220 W input power. Expected output power would be about 110 W, or 50% overall efficiency. The PA can be loaded to higher than 340 mA, but that is the maximum recommended by Drake to meet "Purity of Emissions" standards of today.

Doncha' just hate intermittents!?!??! :-) Your 4.4 V p-p output from the BM sounds like you have plenty of audio. Is your output being limited by the ALC, i.e., does the output go up as you increase the GAIN and then 'flatten out' around 10-11 o'clock? Once this happens do you then adjust PLATE and LOAD controls for maximum output? There have been some problems with leaky 12AX7s in the ALC at V1b.

Interesting. I have had "new" transmitters come in with _completely_ dead Finals, even though the filaments were lit. I found that hard to believe, but ... One possibility is that the Screen is being damaged, shorting to the Suppressor somehow.

> YIKES!! You have been busy..... :-)

I work on this thing intermittantly partly because of
my work schedule and and partly because I get burned out on
it. I sent you another e-mail later in which I said that the
levels at the null pot wiper were much lower than I stated,
I was going by memory, or maybe they were higher. I also
rechecked the ripple on the power supply. I thought it was
reasonable on the HV but had not checked it under load. With
the TX tuned up to maximum output there is a lot of sawtooth
ripple on this supply plus the voltage goes down a lot. The
original filter caps were dead and I replaced them with caps
at hand. Perhaps they are not so good. I have the Heathkit
Shop kit and will begin to assemble it today. I don't think
it pays to trouble shoot further without starting with the
supply.
The ALC flattens out on Tune but the audio from the mic
does not get up that high. BTW, its not the mic, I have
several and all are the same. I will probably repace the
coupling caps in the audio path later. While the current
caps are ceramic and probably OK the only way to know for
certain is to replace them. I have good film caps and will
also increase the size a bit to improve the low end. BTW,
the lower audio frequencies are _very_ limited, more than I
think is normal even for this TX so that may also be a clue.
I think the resistors I replaced probably drifted up
from age but comp resistors can get quite hot without
looking burned so there may have been some overloading. BTW,
the cathode resistors were of two different makes; one was
an Ohmite the other an unknown but with mold marks running
the long way on the case. The Ohmite was still within specs
although just barely but the other had drifted up to about
75 ohms. A million years ago, when I built a lot of stuff,
Ohmite had the reputation for being the best of a bad lot.
IRC resistors, the ones with the rough surface, had a
reputation for being noisy. Film resistors, mostly deposited
carbon types, were available but mostly as precision
resistors and were very expensive.
More when I get the power supply done and can make some

measurements with it.

Richard -

I think the best carbon comps were A-B. They had the smooth body with smooth ends and bright color
bands. That is all I have ever seen in Drake gear. I suspect your Ohmite was a previous "fix".

Don't get too carried away increasing the low frequency response. The specified response is 350 to
2400 Hz, and if you go much lower than that in the audio stages the distortion and carrier suppression both suffer. If you have poor low frequency response on one sideband, check and ensure
that you don't also have poor high frequency response on the other sideband. A CO that is off
center will give that result. I assume you understand that voice peaks are very short in normal
speech, resulting in very low "average" meter readings. The meter in the T-4XB is pretty heavily
damped, which makes it slow to respond to peaks. Unless you have a scope or peak reading wattmeter
the best test is a steady whistle or broad "aaahhhhhhhhh" to see if the meter reaches the same
current it does in TUNE.

Typical AC-4 should have 650 VDC under full load (350 mA) with less than 1% ripple (6.5V p-p),
soaring to almost 740 VDC with no load.

Just keep telling yourself, "We do this for fun", "We do this for fun", "We do this for ..." :-)

I will recheck the HV, that is more ripple than I
thought was normal. I found a mod somewhere about increasing
the coupling caps. The limited response is on both sidebands
and AM. I think it may be connected to the low gain problem.

I can replace the coupling caps one at a time with new ones
of the same value and see what, if anything, happens. There
are some other mysteries but they may be artifacts of
working when I am tired.
Its beyond fun, its obsessive-compulsive:-)

Yeah, the "Hi-Fi" crowd thinks an SSB _COMMUNICATIONS_ link should sound like the local FM _MUSIC_ station. They spend thousands on limiters, clippers, equalizers, compressors, and "wide response" capacitor and other exotic microphones. So they can sit and discuss their latest surgery with FULL FIDELITY, regardless of FCC regulations and common consideration.

Sorry for the rant.

Anyway, the standard response of the T-4XB or C is optimized for communications and if properly aligned and adjusted correctly WILL meet FCC "Purity of Emissions" and "Minimum Bandwidth for Effective Communications" regulations. The absolute bandwidth is determined by the passband of the filters, so just widening the Mic Amp response won't have much if any effect, unless it is MORE restrictive or offset with regard to the filter passband.

Joe -

Don't lube anything except the motor! The only lubrication should be inside the motor "gearbox",
which is either glued or soldered shut.

The wheels and shaft should be clean and dry. Be CAREFUL cleaning them. Water only. Windex and
just about any other "cleaner" will take the numbers right off.

You can adjust the little beryllium springs inside the rim of each wheel to center the numbers in
the window and line them up.

The soldered gearbox can be opened with no "sproing-ing" if the motor is slow. Sometimes cleaning
out the old grease and re-lubing with Lubriplate or such will free up a motor that is slow or hot.
However a hot motor usually means a shorted turn. So far as I know, no-one has offered a replacement motor. Biggest problem is that EVERY other clock motor I've found runs in the opposite
direction!

The Penwood "Numechron" desk or "TV" clocks are the same unit, and those still show up from time to
time......

3409. R4B distorted audio

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-03-28 02:48:39 UTC
From: ejj@suddenlink.net
Topic: 3409 Message: 3409

Hello All
I just purchased a R4B. It apparently had been in storage for an unknown length of time before I acquired it. The seller said the radio ran fine. It is in excellent physical condition and ran fine for a few minutes then the audio became distorted. No hum. Sensitivity good. All functions appear to work fine. It suddenly improved when I rotated the off/on/standby switch thru positions. I used some contact cleaner on the switch and reseated tubes. Now the radio has distorted audio with occasional popping sounds all the time. The audio is ditorted thru the headphones as well.
I know electrolytics are always suspect on old radios. Any advice troubleshooting would be appreciated. Is there a source for caps for these radios? I purchased a 2B re cap set awhile back from N0JMY, I beleive

Thanks

Possibly the cathode bypass cap on V7, C176. You can just disconnect it, just reduced audio. Check voltages around V7. Of course C90 is also a likely suspect!

Tom at Hayseedhamfest.com may have cap sets for the R-4B. He is having supplier trouble, but has some in stock.

I have almost always found a bad resistor when there is "popping" usually because of hair-line fractures. Sometimes they're easier to find when tapping around the components; they usually appear after the unit has warmed up and helped to increase the separation in the crack.

best of luck, Grant

Have you tried another tube?

Here is a reduced resolution photo from the CD, locating C176. I'd start by measuring the DC resistances around V7, power OFF and unplugged. Then disconnect one end of C176, (easiest to desolder or cut lead at the tube socket,) and see if that helps the distortion. Also check R43, (on terminal strip just in front of V7,) and R136 (across base of Twist-Lok cap,) for value and condition.

If still trouble, check all voltages on V7. Does the popping decrease with AF GAIN at CCW?

3414. ac-4 power supply upgrade

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-03-29 03:49:27 UTC
From: Eric
Topic: 3414 Message: 3414

I got the power supply update from the Heathkit Shop.
all went well but i cannot get any bias voltage. I rechecked the connections and parts placement and all looks good.
Does anyone have any hints and kinks to help me out?

Eric -

Verify the polarity and positioning of D7 and C5b and C5b. Neither end
of C5a is connected to chassis, and C5b has its (+) lead to chassis.

OK. C176 has excessive "leakage", meaning there is more DC current flowing through it than normal. Typically it should be microamps, yours is probably milliamps. This is enough to shift the operating point of the tube, putting it into the non-linear area. Not good! It is a bear to replace, but a NEW 10 uF @ 25V is about half the size of the one that's in there, so just thread it in, patiently. :-) You should get a new tube, as that one is quite likely gassy from being overloaded, probably for a while. It's probably drawing more current than it should. Check the voltage on Pin 1. If it's more than about 4.5V DC, the tube is damaged.

I wouldn't worry too much about the resistances on Pins 6 and 7. They are highly dependent upon what kind of meter and polarity of leads used to make the measurements. If you reverse your ohmmeter leads, or use another ohmmeter, you might find a situation where they read what's shown on the chart. I just learned the other day, (after 50 years!,) that there are readings on that voltage chart that ONLY match IF you use a Vacuum Tube Volt Meter (VTVM) to make them. Serious differences, like from e.g., 1.4 VDC to 7.6 VDC.

It would be useful to generate new voltage and
resistance charts. I found, for instance, that the
resistance chart for the T-4XB shows that pin 1 of V1 shold
be 15K. However, this goes to the 150V regulated line
through a 150 ohm resistor and the plate of the regulator
tube, V7, is shown as being 11K. Can't be and is
inconsistent within the chart. Actually, I get about 6K at
both points. I have not calculated the spproximate
resistance that should be there because the 150V line goes
too many places. However, the voltage on this line, and at
the the tubes, is about 149.something volts, just what one
would expect. I've also run across some other
inconsistencies in the resistance chart.
Since all of this equipment is quite old now one would
have to make readings of several known good working
transmitters and receivers to get typical readings. Perhaps
those with equipment and some time could make such readings
and they could be posted to the list or to someone who would
volenteer to produce the chart. Averaging the readings, and
eliminating those which appeared to way out of the average,
could produce a reasonably accurate chart. Both voltage and
resistance charts are useful. The measured resistance will
not depend too much on the meter although the test voltage
and polarity do have some effect in some circuits. Voltage
readings should be made with appropriate meters, probably
all electronic meters with high input impedance.
BTW, some care is needed in measuring voltages in some
older equipment because some voltages were measured with
very low resistance meters, around 1000 ohms/volt and others
with VTVMs with about 10meg input resistance. For instance,
the voltage chart for the Hammarlund SP-600-JX (all
versions) has DC voltages measured with a 1000 ohm/volt
meter except for the AVC grid bias voltages. In many places
the use of a VTVM or 20K ohm/volt meter will give
misleadingly high readings.

Seeing I haven't been able to pickup an RV-4C yet for a reasonable price I have been considering using one of these (in one of the various kit forms which are around) to construct an equivalent.

Also seeing that I might pick up a r4c/t4x combination very reasonably I have also been thinking of building and equivalent to an FS-4 (which on ebay at the moment, when available are going for some ridiculously high prices.

Anyone done this to anyone's knowledge ?

(I would rather NOT reinvent the wheel as such:)

Hi Gary -

There are quite a few actually, no need to "reinvent" unless you just
like those sorts of things. Gets me into trouble all the time! :-)

This is a nice little kit, very inexpensive.

<http://www.qsl.net/k5bcq/Kits/Kits.html>

Someone did an article in QST a few years back using an AD DDS chip to
build a "pseudo" FS-4.

There have been several other units offered, but were quite expensive
and didn't seem to last long.

Thanks Garey,

Actually that was the kit I was thinking of :-)

I don't subscribe to QST, it isn't cheap downunder
and rare to be seen nowadays on the news stands for even browsing.

I should go an look at the ARRL site, I haven't looked for ages ....

3421. MN-2000 Tuner

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-03-30 04:32:20 UTC
From: Carl McLelland
Topic: 3421 Message: 3421

Here's a different question to test y'alls knowedge.. I'm using my MN-2000 tuner on an Icom 718 until I can overhaul my T4XC, and go "analog"..

Here's what I would like to do, and if there's a way to do it I'd sure appreciate info on how to do it... In the next couple'a weeks I want to get a G5RV antenna, and ground it so I can get up to 160 meters. Unfortunately the MN-2000 only tunes from 10 meters to 80 meters.

1. Is there any way to modify, or otherwise make the MN-2000 antenna tuner work on 160 meters?

Thanks in advance; all your help is appreciated..

3422. AC-4 modification and T4XB

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-04-01 08:53:32 UTC
From: Richard Knoppow
Topic: 3422 Message: 3422

I just got finished installing this mod in my AC-4. The reason was that I thought the AC-4 was not behaving right. I was getting something like 30 volts peak-to-peak ripple on the HV when under full load, a nice saw-tooth. I thought perhaps fixing the supply might cure some other problems. Well, the new supply works mostly like the original except that the 250V regulation is a lot better. I think this also had rather high ripple on it. I still get 30V p-p ripple under full load.

I did find another clue about the "low gain" problem in my T4XB,

about which more below, however, I want to comment on this modification, which comes highly recommended.

In fact, it works. However I found the instructions left a lot to be desired. The first part, assembling the circuit board went fine but the second part, clearing out the old circuitry and re-wiring, has some quite confusing stuff in it. For instance, I did not need to install the extra terminal strip. I also found that a couple of wires mentioned seem to come from no-where and are not needed. The lack of drawings or photos makes life difficult in a couple of places. Fortunately, I had sketched out the original layout. A photo would have been better but I don't have a digital camera at hand. I also find the repeated warnings not to blame them if you kill yourself a bit much, I suspect the fellow has had some bad experiences with brain-dead customers.

In any case, the components supplied seem to be of high quality and the circuit board is well made. I strongly recommend that you make drawings of take photos of the original chassis layout before starting and do a dry run before undertaking the actual work. That will show up any gotchas in advance. I actually did a sort of dry run but didn't go far enough.

All in all I would recommend the mod to those who's AC-4s have thrown a shoe.

Now, about the low mic gain. I did a lot of checking including measuring all the resistors in the audio path. I did find a couple that had drifted but not enough to cause the trouble. I was mis-led into replacing a couple of perfectly good caps. While the film caps in Drakes may go bad sometimes they seem to have used very high quality parts so I suspect that actual failures are rare.

By accident I discovered that if I put the function switch in a sort of half-cocked position between tune and

SSB it evidently disables the AGC and, voila, there is plenty of output! Of course, there is no level control. This makes me think there is something wrong in the AGC circuit. I did replace some resistors in the final and in the plate current circuit as recommended in a sheet with levels in it sent me by Garey. I found a couple that were way off. I have also replaced the cathode and screen resistors in the final. I checked other resistors in this circuit without finding any that were way off but may have missed a couple. I have to analyse this circuit further to see what I may have missed.

For Garey, the new supply does not increase the output much. I get about 110 watts in tune and about 140 watts in CW testing at 7100 khz. I am not sure what to expect but think this may be a bit low. At minimum load the HV is around 690 volts with less than 10volts p-p ripple. At full CW output it drops to about 650V (the old one dropped even more) and ripple is about 30V p-p as mentioned above. Is this normal??. If it is I don't want to be tilting at yet another windmill. At full out on Tune the voltage is not down much, can't remember exactly and didn't make a note and the ripple is not much more than at minimum power, perhaps 10V p-p.

Anyway, any suggestions (other than soaking my head) would be very welcome. I am giving up for today (tonight). This is a "day" off for me and I intend to get some sleep and enjoy the day tomorrow.

73 to all and I sure hope someone has an idea.

Subject: [DrakeRadio] AC-4 modification and T4XB

I re-checked output voltages on my modified AC-4 both
without load and under load.
Without any load, that is, disconnected from the transmitter
I get:
HV about 680V, this is within the specs of 650 to 750V.
Drops to 615V under full load (CW maximum output) with high
ripple, about 30V p-p.
250V supply, specs say at least 290V I get 277 and it drops
below 250 under load. Ripple is about 1V p-p.
Line voltage adjusted to 117 with a variac.
I've assembled the thing correctly, have no reversed
diodes or caps.
This is just about the same as I got with the original
set up including my makeshift replacement for one of the HV
caps.
Is it possible the new caps could be sour? I am
interested in other's experiences with this mod.
Both supplies use voltage doubler circuits which are
more sensitive to load and capacitor condition than a full
wave rectifier.

Hi Richard, You said, “For Garey, the new supply does not increase the output much. I get about 110 watts in tune and about 140 watts in
CW testing at 7100 khz. I am not sure what to expect but think this may be a bit low.”

In the manual for the T-4XB on page 3 it states, INPUT POWER 200 watts PEP for SSB and AM, CW is listed as 200 watts. You have to remember this is input power not output power. Also as you go up in frequency the output power will drop.

On page 18 the forth paragraph talks about the difference in operating conditions between TUNE and CW. It says, “The power output may be lower in the CW position for a given setting of the GAIN control.” For some reason your getting the reverse, more in CW mode. Is it possible you have the outputs reversed for TUNE and CW?

Also there is a chance to the tuning procedure that was published many years ago, see below.

T-4Xany Tuning Alterations

On the T-4, T-4X, T-4XB, and the T-4XC there is a new tuning procedure. The tune up procedure for the T-4 series transmitters must be altered from the instruction manual in order to meet section 97.73 of the F.C.C. regulations which concern the purity of emissions.

Tune up on 160, 80, 40, and 20 meters must be altered by limiting the plate current to 340 milliamperes with the LOAD control. In stead of adjusting the LOAD control for maximum FR output, the LOAD control should be advanced from CCW to the point at which the resonant plate current does not exceed 340 milliamperes.

The tune up procedure in the instruction manual may be followed for operation on 15 and 10 meters.

The tune up procedure in the instruction manual may be followed for operation on 15 and 10 meters.

Al, n7ioh
Payson, AZ

I am not sure what the power output should be in tune and CW. I think Garey said it should be about 130 and 150 watts but have to find that e-mail.
For the _same_ setting of the gain control the output in CW IS lower than tune but, the gain can be turned up. At some point the AGC prevents increasing drive in Tune, in CW the drive can be increased more and by juggling the load and plate tuning the output will go up. Probably this is driving the final into a non-linear state where its producing spurs or harmonics. The "new" tuning procedure mostly is to limit plate current to a value where, presumably, the final is _not_ generating distortion products.
I may be expecting too much of the thing.
I have at this point two problems: on is the "low gain" problem. I put quotes around this because I think it is actually due to the AGC, not the audio stage. The other problem is that the voltage out of my AC-4 with brand new Heathkit Shop modification in it is lower than their spec. I have obtained some new capacitors locally and will try them in the circuit later and report. I don't think its the transformer because it doesn't run hot and is not noisy, both symptoms of problems. I have yet to measure the open circuit output voltage of the transformer itself but will do that if the new caps don't cure the problem. Remember that this kit includes all the capacitors and all the diodes used in the power supply. I do not have anything turned around, I've checked several times plus reversed caps will blow up after a relatively sort time.
I do have a clue about the low audio. The AGC buss is carried out to the power supply where it is terminated on an RCA jack for use with Drake power amplifiers. Its a convenient place to make measurements. I found that the impedance ot this circuit is enormously high, high enough to be loaded by electronic voltmeters with 10megohm input. I do have a meter that can be set up for a much greater impedance. That is a General Radio 1800A. It can be connected for open grid measurements provided it can be zeroed on the actual load. This is an input impedance of around 100 megohm or more. It will tell me what this circuit is doing. I find if I _short_ the AGC buss the audio drive goes up tremendously providing full SSB modulation with the gain control about half way up. Of course its easily overdriven. I have some more resistors to check in this circuit. The answer is there somewhere, its just eluding me and requires a lot of patience.
Another shameless plug for Garey's disc. I printed out the "handbook" he has with photographs of the interior of the transmitter and receiver and also had the schematic printed very large scale. Without these I would be completely lost. If you contemplate working on any Drake stuff covered by his discs they are not only wise but

necessary and are not at all expensive. (Garey, you will get
an advertising bill in the mail).

Gary, even a true Sherwood modded R-4C, isn't necessarily worth all of that. One with the full mods, in true MINT condition, could be worth close to that, but few are truly MINT. For you, if it included shipping, it could be worth it, if the T-4XC and MS-4/AC-4 were included. But, I would rather pay $300 for a complete 4B line, and then have Jeff Covelli, or one of the other fantastic tech's go through it, for a couple hundred bucks. Which is how I got my "B-Line" going well.
That price is ridiculous, to say the least.

Why the need to "bash" folks? I see the eBay paostimngs as a source of information - sometimes nice photos - a way to see new (to me) rigs close up - when they sell or do not sell, then it is a gauge of a market place. As the saying goes, "You can't blame them for asking." But we have the pleasure of watching.

He IS serious! These radios sell for unbelieveable prices in Europe, from Iraq northward to the North Sea. These buyers must be missing a few marbles (IMHO). The Drake 4 line is a nice setup, but only 6 to 7 hundred nice.

Kris,
I don't see it as bashing anyone, it is simply commenting on what we see as something out of the ordinary. If we were to be sending the seller, mean spirited messages about the selling price, that would be bashing. A seller has every right to ask whatever price they believe will be fetched, just as we have a right to believe any price we think is outrageous, to be so. Bashing would be those who do not like the asking price, commenting to the seller, in a negative manner, rather than in an advisory manner, or between themselves. But, it is not informational, when someone's asking price is far out of the norm. It is much easier, to watch the selling prices on http://www.joetracker.com/prices/drake.htm . That gives a far better running average of the selling price.
Now, I would guess, from what I read there, that the seller likely has no idea what they are truly worth, or has limited experience with selling these radios, and has an inflated view of their worth, due to some outside influence. The rest of the listings show that they seem to be more geared to selling recordings of old radio show broadcasts, not ham radio. It is possible they are a consignment seller, and are only asking what the owner is asking, in the way of selling price.
Hey, if it sells, they did the right thing, but likely, it will not sell, with that starting price, and they will be forced to re-list it, at a more realistic price. I don't think anyone here is faulting them, only commenting on how "Out of the norm" the starting price is, based on the condition of the rigs, AND our knowledge of the true values of these radios. We'll see what happens, and where it goes, or doesn't.

I wonder if it is the same knucklehead ham that tried to sell me his Drake twin setup for $850.00 plus $125.00 shipping?

Were a lot of people get stung, is the shipping. Tell someone ill sell them a Drake Tr-4 for say $350.00 for the rig, power supply, and speaker then charge them $100.00 to ship. The last time i shipped out a Drake setup i paid $45.00 to ship all of it. It always burns my butt when i see someone that tries to make $$$ of the actual shipping.

Eric,
Likely, it could be, it's a far smaller world in the arena of e-trading and selling of ham radios, than many of us think. I think most sellers have a pretty fair grasp of equipment values, but some folks are a bit "deluded" into having an inflated sense of value.
However, shipping is a pretty subjective thing. Too many variables involved. Each company has their own set of rates, based on how they will ship it, and so on. For me, with my discount, it cost $82, to ship my "B" Line from SoCal, to Jeff Covelli, in the Cleveland, Ohio area, via UPS ground. I don't remember what FedEx and USPS wanted, but UPS was the lowest price I could find, at the time. Yet, to send that MS-4 (without the AC-4), to Gary, Down Under, UPS wanted $175+, and FedEx wanted $182+, where as the USPS did it for $65, I believe, and it got there far faster than either Gary, or I, expected. I think it was there in 5 business days, if my memory serves me right. Not bad, for going clear across the big pond to the west of us.

This **is** getting away from something serious about Drake, but I will add one thing many are not aware of.

(And this definitely does not apply to this eBay sale of $975.00, which considering the copper fungus, is ridiculous!)

eBay does NOT charge a fee for shipping...so....Some, like me, ask a lower bid or reserve BIN price and charge more for shipping, so we, as sellers, do not have to pay as much to eBay for their service. I try and price things I sell so the buyer still pays the price I wanted to sell the item for, but I pay less to eBay because of the shipping. It's a profit thing! HEH!

That makes sense to me, Joe. I don't think anyone would be upset about paying a higher shipping cost, if the price were lowered, as you describe. It's a guessing game, in an auction selling format. I never figured out a system for that, that works most of the time, and being the capitalist that I am, I just sell, and hope to make enough, that after eBay's fees, I am getting what I want to pocket. It's the "Cost of doing business", as my professor, once taught me, in my hospitality management course.
Personally, if it all works out in the end, I see nothing wrong with your method, but, I've never charged more in shipping than it actually cost me to ship, +/- a miniscule amount, because the shipping calculators aren't always totally accurate. But, I can honestly say, I have had shipping charges that cost me more than I charged the buyer, SEVERAL times, simply because, if I quote a price, I stand by it, even if I wind up taking it in the shorts. I don't want folks to think I'm trying to gouge them, by asking for more than I had quoted. I once sold a Heathkit Apache to a fellow in Tennessee, and quoted a shipping price of $80. In the end, shipping cost me $148. Lesson learned, the hard way.
Anyway, enough on this eBay stuff. We all have our methods of selling, and if it includes eBay, most everyone has their "tricks" that they believe will maximize their price potential. As long as they are ethical, I see no problem with any of them.

I want to wish one and all a Happy Easter, or a Blessed Passover, if you are so inclined to honor either of these Holidays.

Don suggested intro,

I am Ivan Shapiro. KB1STH . I live in Maine. Recently licensed (finally after yrs of doing nothing).

I☐m on an accelerated path, trying to learn as much as I can as soon as I can.

Recently acquired a set of twins (R4B/T4XB/MS4/Drake Tuner/AC4/WS4 meter)

An Elmer helped me get it going. I need to learn how to Tx on it.

Also have FT-950-1st rig.

Bought IC 746 Pro used from a friend.

Putting IC7000-Tarheel Antenna-Turbotuner in truck.

I think the ham bug really bit me hard.

So why Drake? I thought it worthwhile to learn how I would have worked ham radio with tubes, years ago.

When I was in Columbus OH last yr I stopped by UniverfsalRadio. One question I had was what tube rig should I look for.

They had sold their twins, but recommended I find one.

Oh one more thing. I☐ll probably find a good L4B some day.

Thoughts? Comments?

Would be welcome.

Do you have the handbooks for the receiver and transmitter? If not there are decent copies on the web or you can get a disc from Garey Burrel with very good resolution versions plus a lot of other stuff which was not published by Drake.
The handbooks will tell you how to wire the RX, TX, and power supply together. You have everything you need listed above except for an antenna. I assume you have a microphone and key.
The main caution, and this applies to transmitters generally, is to go slow when tuning up. Increase power very little until you have just enough to get a reading on the plate current meter. Then tune the plate tuning for a dip. Then make sure the drive is peaked. You may have to peak the drive first to get an indication if its off very much but the gain control should be very low and back it down as soon as you get an indication so that you don't exceed the plate current. Once you have the plate dipped you can increase power and adjust other things.
You can use the receiver to rough tune the antenna tuner. It will give you a peak output when you are close. Tuning should be done with low power to avoid interfering with other stations. Keep a record of the settings for each frequency so you can return to it.

That's enough for now. Most of this is spelled out in
the handbooks.
I also recommend getting a copy of the _Radio Amateur's
Handbook_ from the ARRL, it can be ordered over the web.
Lots of good information in it mostly well written.

Terry -

There are several differences.

The R-8 is a fairly "stripped down" model compared to the R-8A and R-8B. There is a full page of additional features (some of them important) on the last two versions.

The R-7A is the "top" of the 7 series, sold toward the end of production. It includes the Noise Blanker and CW filter standard, both of which were optional in the R-7. Of course the R-7A is capable of transceive operations with the TR-7 as well.

Aside from their place in history, the R-7/A is a top of the line communications receiver, while the R-8 is more of a top flight SWL receiver, even though my R-8A says "Communications Receiver" right on the front panel. :-)

From: larfla2
Topic: 3452 Message: 3452

Hi guys,
I'm going into my R-4B and T-4XB to do a few checks and updates. Check alignments, install a outboard digital freq. counter, change out the VFO NE-2 and board on the R-4, new finals, etc. My question is about neutralizing the finals. I usually (on other tube rigs) do it with a scope after disconnecting the plate and screen. Is it ok to do it this way on the Drakes? Where do you guys recommend disconnect, if so. Thanks for the input. Larry, W2DDG

Thats the way I have done my A and B models. The easiest spot for me to disconnect is at the feed-thru caps/bushings on the Final side of the bottom chassis partition. Its where all the power comes thru the partition to the bottom of the final compartment.

BTW..you can get it real close just by watching the dip in Ip while looking at the output into a dummy load with a scope.

FWIW

Curt

Richard -

If you have a TV-7, you need

Download <http://www.antiqueairwaves.com/nlee/files/tv-7_097.zip>

Excel file with just about any tube.

6HS6 6.3 ET1-5627 / Bias 11 / Range D / 3 / Min - 28 / Best seen = 40

73, Garey - K4OAH
Glen Allen, VA

Drake 2-B, 4-B, C-Line& TR-4/C Service Supplement CDs
<www.k4oah.com>

Does anyone know the settings for the 6HS6 tube for the
TV-7B/U tester. The tube does not show up in any of the
updates for the tester, perhaps it was too new, the last
update seems to have been published in 1972.

Hi Lee W0VT,

Just for fun, I also downloaded this file. It opened on my Mac using "Numbers" just fine, all data present (at least I think so, it opened with about 9 pages including preamble and TOC <grin>). If I were having your difficulty I'd try the file with another program and see if you get the same results, which are very weird.

Have fun and good luck!

To Garey Barrell,

Just as an aside, from a very old post, I just recently sent my 31xxx series TR-4 to Jeff Covelli for refurb. From what I've read, he's quite good, and does a thorough rebuild for a fair price <grin>. At least I hope so. No rush anyhow, as my Drake is a shelf unit standby (at least until I get it back. It's such a good radio when it works, I might upgrade it to primary <grin>).

Thanks a bunch all, for all the good ideas here.

Thank you Garey. I did a pretty thorough Google search last night but it didn't find this. The data seems very complete plus the transconductance chart should prove valuable.

I discovered I had this tester the other day when I found it in a storage garage (my life is in storage). Mine is a bit beat up but seems to work fine. I don't clearly remember where I got it, probably some surplus store cheap because if its dented up appearance. I don't have any of the accessories but the test leads are easy to make and are the really necessary ones. It has the original databook. I found both normal and depot service manuals on the web plus updates for settings but this chart seems to include settings that users have determined which go beyond the official ones.

My other tester is a Weston, also a mutual transconductance tester, but it does not do the gas test and has a more limited range of tubes. I did not realize that the TV-7 is considered such a valuable instrument but can seen why. BTW, mine is a TV-7B/U made by Foreway.

I also have an RCA tube tester than uses punch cards but there are only a limited number if cards for it. I have to get that out and see if it does compactrons. I think I also have a couple of other testers but am not quite sure

which, maybe a Heathkit and also possibly a Hickock.
While the stuff I have in storage was put in neatly
both have gone through a couple of earthquakes which have
made scrambled eggs of the stuff inside. Nothing damaged but
beyond my physical prowess to re-arrange in order. Some day
I will hire a crew to help with this and, at the same time,
get rid of the junk.
I am still working on a problem on my T-4XB but want to
try a few things before yelling for help again. However, I
think the low microphone gain problem, at least on mine, is
actually an AGC problem due to leakage somewhere. Again, I
am still working on this but I suggest to others that have
posted with a similar problem to compare SSB to AM. If you
have enough gain in AM the problem is probably not in audio
circuit. Another clue is to short the AGC line and see if
the gain goes up to normal in SSB. This is most easily done
at the RCA jack on the AC-4 supply that is intended to feed
AGC to a power amplifier. If the gain goes up to normal
(full modulation) the problem is probably in the AGC.
It would have been nice to get a T4-XB with fewer
problems but I have gotten a very liberal education out of
it.

Tested 2B S/N 9611 as follows:

Per suggestions and notes in the CD, I measured voltage at the mute terminals using VTVM with 2B in standby. RF gain at max the voltage is 7VDC, RF gain at minumum it is 15 VDC. Removing V1, V2, V4, or V5 makes no difference. AVC in slow, the voltages range from 8 to 15. Evidently the tubes are ok, The AVC is set per the instructions. Any other ideas?

What happens in FAST AVC? If the voltage goes more negative, or if the receiver mutes fully, you may have a leaky cap at C68. A contaminated (WD-40 or other contaminant sprayed in it?) STDBY - RECV switch. It's a challenge to understand just how high impedance this circuit is.
Doesn't take much voltage to hold it down.

Just to avoid overlooking the obvious.... Have you tried substituting V1, V2, V3 and V4? AVC2 is applied to each of these, and is what is supposed to cut them off in standby.

Nine volts should be more than enough to cut off all four of those tubes. You may also have a resistor that has gone up in value. Check the voltage on V1, Pin 1; V2, Pin 2; V3, Pin 7 and V4, Pin 7. Each one should be about -6 to -8V with the receiver in standby.

3471. Re: Drake 2B Inadequate muting

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-04-12 14:07:12 UTC
From: russellhulett
Topic: 3450 Message: 3471

No, I have not tried substituting tubes, just pulled one at a time to see if any were pulling down the voltage. AVC fast the voltage is 7-15, AVC slow it is 8-15. Just to be clear, I've done nothing with V3, the CD talked about V1,V2,V4, and V5. Is V3 also potential issue?

I am noticing that the Standby/Receive switch may be less than perfect. I don't like to use deoxit or wd40 or other "cleaner" without VERY good reason. In fact, I'm not much of a deoxit fan in the first place. Especially with these slide-action switches, afraid of making things worse not better. How do you deal with dirty switches?

I'll check the tube voltages as time permits today.

Thanks again, 73 Curt KB5JO

Curt -

No, my mistake. Too late! :-)

V3 is not on either AGC bus.

I agree on the "cleaning" products. DeoxIT is pretty reliable if used
in liquid form, but can be a contaminant and/or dust catcher if sprayed
indiscriminately. You can lift the wire from the switch, either
terminal, to check.

Before you do that, try measuring the voltage on each grid mentioned
below, substituting Pin 1 of V5 instead of Pin 7 of V3. You have plenty
of AVC voltage to cut off the receiver, so we have to find out why this
voltage is either not getting to these four tube's grids - or - why this
large negative voltage is NOT cutting off one or more tubes.

3473. Re: Drake 2B Inadequate muting

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-04-12 19:07:41 UTC
From: russellhulett
Topic: 3450 Message: 3473

After checking the voltage on the AVC line at the respective tube pins (V1 pin 1, V2 pin 2, V4 Pin 7, V5 pin 1), all are the same, only now at -6VDC to -15VDC RF max gain - RF Min Gain, Standby. I pulled tubes one-at-a-time, replaced with other tubes, no change.

I'm concluding that whatever is dragging down AVC voltage isn't associated with the tubes. And, the available AVC voltage seems to tail off the longer the receiver is turned on. I noticed when using with the T-4XB that the muting seemed to get less reliable the longer the receiver was turned on.

I measure the AVC line and mute line resistance at 10.5 megohm.
Pin 1 of the 8BN8 is -21 VDC. Instructions state that should have
-9VDC to mute and appears there is less than -6VDC at maximum RF gain.

73, Curt KB5JO

Curt -

Perhaps I'm misunderstanding.... When in STBY, the voltage on the AVC line should go to -9 or greater at the AVC terminal, regardless of the position of the RF GAIN control.

Does the receiver mute completely when you turn the RF GAIN to Min?

3475. Re: Drake 2B Inadequate muting

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-04-12 20:16:49 UTC
From: russellhulett
Topic: 3450 Message: 3475

On this 2B, when in STBY, the voltage at the AVC terminal (and the Mute terminal) varies from -6 VDC with RF gain at maximum to -15 VDC with the RF gain at minimum. As I look at the schematic, it looks to me like AVC2 line does vary as RF gain pot is changed.

Nope.....

IF the MUTE terminal is "open", and the STBY/RCV switch is "open" the RF GAIN control is just in series with the -21V supply to the tube grids. The tube grid terminals should draw NO current, therefore NO drop across the RF GAIN control regardless of position. ALL of the voltage divider resistors to ground are lifted by opening the switch.

You have leakage to ground somewhere on the AVC2 bus. The terminal strip, switch, tube socket or wiring insulation is breaking down somewhere.

It only takes a few microamps of leakage current to drop that voltage. I have seen tube sockets or phenolic insulation board that has been sprayed develop much more leakage than that.....

If you are suspicious of the switch, I'd lift the wire to check. 10.5 Meg resistance to ground from the bus would account for dragging the voltage down to less than half the -21 V.

Thanks Garey, I'll just start lifting AVC2 connections, starting with the switch. Maybe someone used deoxit on the tube sockets? I've heard of folks doing that. Just curious, what would you rate probability of finding and correcting the problem? I had one fellow tell me the 2B mute circuit was a nightmare that would never end, working on it was a waste of time and the 2B was best used for SWL.

Curt -

Anything can be fixed. The 2-B is a terrific receiver, and deserves repair.

Perhaps if you don't understand (or believe?) Ohm's Opinion, then maybe not.

It's just a matter of patience and doing something for a reason, by deduction, not just "shotgunning" tubes and parts.

Any unsealed phenolic can become contaminated with so-called "cleaners". Usually the only way to recover is to replace them. Once you determine what the problem is, THEN you decide if you want to do what's necessary to repair it.

One other obscure possibility is that the Bias Adj pot (R48) itself gets some kind of gunk sprayed in it that forms a leakage path to ground. I found one of those once by loosening the hardware and letting it "float".

Going back to Mr. Ohm, what do you measure from the MUTE terminal to ground with nothing connected to it? Should read a very high resistance. Reverse the ohmmeter leads and see if the reading changes.

Garey,

I measure 26 megohms both ways with my Voltohmyst from the mute terminal to ground. I've read some about R48 developing a leak to ground as possible cause for muting problems.

I remember having this muting problem in my 1st Drake 2B in 1965 or so. Several weak tubes were replaced and then it was fine again. Like Garey mentions several tubes have the muting voltage applied to them.

My current 2B is working well thanks to this group!

Daniel -

I've never tried this, but it looks like you should be able to just turn XMTR GAIN to minimum and key the PTT. There's probably enough carrier leakage to enable you to tune the transceiver to the receiver frequency.

Actually, if you're in a quiet room, you can probably just key the PTT on SSB, and as long as nothing is picked up by the mic there will be essentially no output power.

On CW, just turn the XMTR GAIN to minimum, and key the transmitter in X-CW.

Actually, you can probably key the transceiver at full power and it wouldn't hurt the receiver front end. The relay isolation is pretty good, and should be enough to protect the receiver. Putting the receiver in MUTE does nothing to protect the front end of the receiver. MUTE only applies cut-off bias to several stages of either the internal or external receiver.

Now IF you were to connect the output of the transceiver directly to the input of the receiver, you'd definitely need a new T1!

3485. Microphony in valves

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-04-14 11:46:56 UTC
From: mike
Topic: 3485 Message: 3485

I know that microphony in audio valves isn't uncommon, but I don't know whether it signifies a fault or should just be tolerated.

I normally use my Drake R-4B rx with the audio gain at max and just use the RF gain control.

I've noticed, especially when wearing headphones, that the slightest touch to the o/p valve (6EH5) or a tap to the rx case is clearly audible.

It's not causing me any problems, but I'd like to know whether I should replace the valve or is the replacement likely to do the same thing?

Thanks,
Mike

I may be wrong but I think you are doing this the wrong way round.

So far as I understand it the RF gain is usually set at max and the level of audio controlled by the AF gain.

As I have never had an R4B I can't say that you are mistaken with the way you are using the controls but I'm sure that the general practice is RF gain at max (unless you get a strong signal that overload the front end) and then adjust the audio (volume) with the AF gain.

I agree that this is not the normal way to operate this RX. I sometimes do back down the RF when strong signals make the AVC pump and occasionally use it in manual gain.
However, I checked my R4XB for microphonics. I used a pair of low impedance (50 Ohm) phones, sensitive enough to hear just a bit of noise even with the AF gain at minimum. With the AF gain at maximum and the RF at minimum I can just barely hear some microphonics from the ouput tube. I can tap the tube with the end of a screwdriver stuck through the ventillating holes in the case and hear it but its not loud and is not audible in the loudspeaker.
You could try another tube but, again, running AF gain wide open is not the usual way to do it. If you _must_ do this there is likely something wrong with the AVC.

Yes, typically the RF GAIN is max CW and volume controlled by the AF
GAIN control. The "max AF, control with RF" was correct procedure back
when receivers had diode detectors that were easily overloaded. In the

Drake receivers, the Product Detector and AVC are designed to deal with this, and maintain a constant AF output with widely varying signal strengths. IF you have a very strong interfering signal that is depressing the AVC, and thus the desired station, THEN you can turn the AVC OFF, increase the AF GAIN and control the levels with the RF GAIN control.

That said, the AF stages in the Drake receivers ALWAYS operate at maximum gain. The output level is controlled by adjusting the amount of audio INPUT to the amplifier stages. Since your microphonic behavior is produced by tapping on the AF output tube, it IS the tube that is microphonic. Possibly a loose element support or similar. Replacing the 6EH5 should solve the problem, assuming the NEW tube is OK. Check the Cathode voltage on the stage, if over or under about 4.5V, you may have a cathode resistor that has gone up in value, (higher voltage,) or a leaky cathode bypass, (lower voltage,) both of which are fairly common in receivers this old.

Topic: 3485 Message: 3490

It sounds as though my valve is noisy, then. The ringing from the electrodes is quite clear and pronounced.

I must stress that everything is fine if I leave it alone. There is only noise if I tap the valve.

The AVC works fine, but I much prefer to run the way I do as it stops the background noise coming up on weak signals or during QSB.

Effectively the AVC is disabled at the low RF gain I normally use, but I have to compensate manually for different signals... not a problem.

Try it! You might like it! :)

Thanks, Garey.

I'll check the cathode circuit later, but it does look as though my tube has a problem.

I've tried running with max rf & controlling the audio, but I find the constantly varying background noise level really annoying, so I run the other way around, which I much prefer.

I can listen to very weak signals quite easily, with only as much noise as is unavoidable. The only downside is that I have to do the AVC myself. :)

From: Forrest Plumstead
Topic: 3493 Message: 3493

I have seen several queries about sudden problems, and the first suggestion is pull the tubes and re-seat them. So when I got noise out of my TR-4 but no stations, that's the first thing I did, and wha-la it's talking again. Thanks for the tip.

I have been having trouble with my sideband switch. I have to jiggle it around before I can get a clean signal from it. Can I use WD-40 to solve this or do I have to have the electronic contact cleaner?

Use contact cleaner. WD-40 leaves an oily residue. I
don't know if its conductive but I think it might be. At any
rate, WD-40 is not an effective contact cleaner.
Opinions vary but Caig products seem to be the best.
They make De-Oxid in a couple of variations. Reports are
that their "Gold" is about the best. However, I suggest you
get the kind that comes in a bottle and not the spray-on
type. The liquid is applied with a small brush or similar
tool and you can control where it goes; the spray goes all
over the place.
I have also had good results by applying Tunerlub made
by GC after using the contact cleaner. I've tried this
combination on a couple of rotary switches which were
persistenty noisy, for instance, the bandwidth switch on a
Hammarlund SP-600-JX. This wouldn't stay quiet for more than
a few days after treating with contact cleaner but has
stayed quiet for more than a year after applying Tunerlub.
Its a light, non-conductive, grease that can be applied with
a brush, the end of a paper clip or other suitable tool. It
also works well for lubricating the ball bearings in
variable capacitors.
The shaft bearings of switches and pots can be
lubricated with light oil. I prefer the synthetic oil
available in hobby shops because it does not become gummy.
Use a minimum amount applied as above with a small brush or

wire pick-up tool. I also use this stuff on the escapement
in camera shutters where it seems to work well and last
forever.

Unless I'm trying to dig out a weak one, I like the improvement in S/N ratio
that backing off the RF gain provides. It can also help with close-in
interfering signals by movng them a bit farther down the skirts of the crystal
fitler. Kind of hard to visualize, but it works.

From: marc k
Topic: 3493 Message: 3496

Actually, the biggest problem with using WD-40 is not that it leaves an oily residue(that is not always a bad thing, btw)-the big problem is that the "oily residue" is basically Kerosene mixed with the sludge that remains after you remove all of the "good stuff" from petroleum.
The Kerosene dissoves the sludge-so all seems ok for a little while...but Kerosene evaporates fairly quickly(actual lubricating oil does NOT, btw).
Once the Kerosene goes-the sludge turns back to it's original form-generally making things worse than they were in the first place.
I've seen the stuff lock bearing races SOLID!
As for Caig-yes their stuff is excellent-their basic product, Deoxit is good-but it's intended more for switches than pots-it works adequately for them in most cases though.
Just watch out with rotary switches-it is NOT a non-residue cleaner.
You can use it on them, but apply it carefully, only where needed-don't "hose down" the switch.
The best product that they make, in general, is the 100% liquid-it comes with a application needle.
It's costly, but if used properly, one bottle will last for many YEARS!
If you were just going to buy one item from Caig, that's the one I'd reccommend.
The product you are looking for is:Deoxit D100.

3498. Re: Drake 2B Inadequate muting

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-04-18 20:22:46 UTC
From: russellhulett
Topic: 3450 Message: 3498

After taking various voltage readings at V1, V2, V4 & V5, reassembled the 2B and reconnected to the T-4XB with intent of measuring voltage at the mute terminals and 2B RF gain necessary to mute.

For whatever reason, muting is now reliable and have been using the pair for CW QSOs without difficulty. Not sure what has changed, maybe the muting cable was somehow shorted, but change has been for the better. The other change was to locate the 2B away from the MN4-C, before it was adjacent to the tuner.

Now .I want those frequencies allocated to extra class licensees.

The jump from general to extra is a huge quantum leap, compared to my initial testing which was tech and general.

There are brand new concepts, foreign to this new ham. Will do my best when I get my head around them.

Study study study

3500. Capacitors needed-TR7

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-04-19 23:35:22 UTC
From: Lorne Barber
Topic: 3500 Message: 3500

I am new to this list so please excuse me if this is common knowledge.

I am redoing my TR7 and I would like to replace the electrolytic caps on the power supply board which is located just behind the front panel.
While I have basically found a sources for all the caps, they come from several different providers.
My question is, is there someone who supplies these in one package?

Lorne,

Not to my knowledge. You might want to contact Tom at Hayseed Hamfest, he may
be interested in puttng together a kit since this is the one area in the TR-7
that should ALWAYS be re-capped (IMO).

3503. low-impedance microphone for TR4C and T4XC

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-04-21 13:20:23 UTC
From: arsnf7z
Topic: 3503 Message: 3503

Greetings,

I understand the high input-impedance of the tube microphone circut, and am wondering if anyone has tried to use a microphone like Heil's Fin or GM series, either directly or with a step-up transformer. or, are the levels such that you need to drive the transmitter with a higher level source from a pre-amp.

before I launch into this venture, it might behoove me to ask if anyone else has attempted same, and hear of their observations. I would love to be able to use the HC-5 in my Heil ProSet Plus, without any additional circuitry involved, but I suspect the levels are insufficient to drive fully. it seems to me that even though the microphone is 600 ohms, the mismatch shouldn't be an issue into a high-impedance load.

just thoughts ... any observations?

NF7Z, daniel

3504. Re: [DrakeRadio] low-impedance microphone for TR4C and T4XC

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-04-21 13:44:01 UTC
From: Garey Barrell
Topic: 3503 Message: 3504

Daniel -

The problem is not just an impedance mis-match, it's a matter of signal level. Low Z mics are typically low level output, while Hi Z mics are much higher output. So the step-up transformer is just to step up the voltage produced by the low Z Heil mic.

The Astatic D-104 with the amplifier base is an exception. The cartridge is high output, Hi Z, and is its frequency response is very susceptible to impedance loading. The amplifier provides a proper, matched load for the cartridge, and puts out enough _voltage_ to drive _either_ a Hi - or - Lo Z transmitter.

maybe you mean "exponentially"? Logarithmically would mean it gets easier as you progress. A log scale is compressed, an exponential scale is expanded.

.....a reasonably priced L4B.

Preferably in N. California or N. Nevada.

The $850.00 tag advertised on QRZ is a bit rediculous..one can buy a well modified Heathkit SB220 amp for a lot less. And it is self contained!

I just want a legal limit amp to match my B Line.

Thanks in advance.

Not without a little more information. What does the radio tell you when you try to transmit? What is your actual SWR (singular, SWRs - with no apostrophe - would mean more than one Standing Wave Ratio)? Does the wattmeter on the radio register anything in Forward or Reflected? Does it transmit normally into a dummy load? Does it transmit normally (into a dummy load) on other 500 KHz segments in the same band range? How are you getting to 12 Meters, do you have an AUX 7 or do you have the "allband transmit" mod? Does the radio receive normally on 12 Meters? Do all the other band segments TX into a dummy load OK?

Gary,

Exactly right!

Also, the price of $850 for a nice condition and working L4B to me is a reasonable price and pretty much the going rate (+/- $100-$200 depending on condition). I paid $850 for my low mileage L4B (5 hours use then stored in a closet) and don't regret it one bit.

YMMV

It does pay to shop around, though. I picked up a nice one that just needed cleanup a few years back from a local here for $450. Tubes turned out to be in good shape, and it puts out more than my L-7.

OK...OKAY!! So I am shopping around....AS I said, my interest is a matching amplifier for my B line. And, as I am basically a cheap busturd, I don't want to pay very much for one...so there!

So now that you all have given me the proper amount of needling..I am still looking for a reasonably priced L4B.

I could go for a $450.00 barn find...err...closet find. (I keep getting my hobbies mixed up..restoring old cars and ham radio..both are things to keep pouring copious amounts of money into...and again, and again, and ag.....)

Remember....N. California or N. Nevada would be nice!

I have a Gregore headset/boom mic that is a low z output on my T-4xc. Gregore solves the drive problem by installing a photo battery inside the headset with a switch. The additional voltage brings the drive level up enough to work fairly well with both my Drake and a Kenwood TS-520s. THey used to sell a small amplifier for their headset for hi-z but have gone to the battery with their mc element instead. I don't know if that will work with your heil or not. I also have an amplified D-104 I use on my Drake.

> >
> > before I launch into this venture, it might behoove me to ask if anyone else has attempted same, and hear of their observations. I would love to be able to use the HC-5 in my Heil ProSet Plus, without any additional circuitry involved, but I suspect the levels are insufficient to drive fully. it seems to me that even though the microphone is 600 ohms, the mismatch shouldn't be an issue into a high-impedance load.

Hi Everyone ,
I recently got a very nice Drake TR-5 . Of course , they're not always the easiest radio to find any information about on the internet . I removed the cover to see if it had any filters in it , and being that I don't know a real lot about this particular radio ... I saw something that brought up a question for me . It appears to have some Crystals missing : Slots 1 , 6 , 8 , 9 , & 11 are empty , and I have no idea if it's suppose to have them or not ... or what's suppose to be in those slots . When I put the Band Selector on 30m , 17m , 15m and the lower half of 10m , the frequency jumps all over the place like it has no way of locating those frequencies .

So needless to say , I decided to place a post on here in hopes that somebody might know a little more about the TR-5's than I do .

Thanks & 73,
Del

Try International Crystal or Sentry.

Maybe Bill Frost might have access to some.

From: MIke
Topic: 3506 Message: 3521

Ok, Jim! Let me take it in order:
No movement of the meter on transmit, but does receive. I do have the allband transmit mod in place, so on that band, I am at a stand still.

And after the rainstorm we had, 10 meter is doing the same. All other bands are ok! So this has to be isolated to the 28.5 switch I would guess!

3522. Drake TR-5 question

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-04-24 21:30:45 UTC
From: kc2mru
Topic: 3522 Message: 3522

I just recently got this rig and before I got it ... the man I got it from said it was not receiving well on 20M (although the "S" meter did not appear to be working) but not on the other bands. He couldn't transmit and hear himself on his adjacent radio on 20M but the Drake showed no output power on his Bird 43. A frequency counter showed the radio to be about 400 hertz off on 20M .

He seemed to believe that the PS-75 might be weak , and that was what was causing the radio to preform like this . I have no history on the radio , and with a radio like this ... I'm not real comfortable poking around without knowing what work might have been done to it previously.

So does anyone here have any ideas ??

OK, that's a good start. If the entire 22-30 band segment is affected, you could have a dirty bandswitch in the lowpass filter section, or a fault in the lowpass filter for 22-30.

I presume you have a service manual. If not, there are free versions available on the internet for download that are usable, although not the highest quality. Google will turn them up, but mods.dk is a good place to look for starters.

I've found it other places as well, but I don't have specifics. If you can't find one, I could send you one or both of the variants that I have if your email accepts large attachments (6 or 7 megs).

How hard is it to find a power supply for an L4B amplifier? I ask, as I am sure, everyone has seen the L4B being sold on eBay...but with no P/S. If they can be had, what can one expect to pay for one...ball park of course.

Still looking for the whole shooting match...Send 'em my way if you know of anyone selling....

Thanks!

Mike -

For only a little more than ModsDK charges, you can get a GOOD, CLEAR CD
with the Service manual for $10 from WB3CEZ.

The photos are clear, not just black blobs, and the schematics are each
one sheet. It prints out just as well if you take it to a FedEx Office
and have them print the schematics on a large format printer.

FWIW, you can "donate" to mods.dk by sending him a good picture of something he doesn't have. You don't get a full year of access from what I recall, but you get enough time to snarf a lot of stuff. I have several pieces of gear "in reserve" to photograph if I have an urgent need.

FWIW, the Hamanuals Drake CD has a very good copy of the service manual as well, with a hyperlinked index to make it easy to find things. This one was the first, I believe, as I purchased it some years ago. It covers most Drake equipment, not just the TR-7. He is under the radar for some reason, most people don't seem to be aware of this resource.
http://www.hamanuals.com/Products.html

There is also an ebay seller that offers a very good manual repro in print or PDF format. I bought one of the print manuals a few years back and forgot that I had it! He has since began offering it in PDF as well.

I strongly recommend having the schematic printed out large. I did that for the ones in Garey's CD, I think I got something like 18"x24" or whatever the nearest standard size to that is. Mine were done at Kinko's but any of the office supply/printer places can do it. I also had the manuals printed out and spiral bound. Its all pretty cheap to do. I find Drake schematics hard to follow, the large size makes life a lot easier.

Yes, although it's getting hard to find something he doesn't have! :-)

It's only $7 I think for 3 months, so certainly well worth it. Most of
the manuals are pretty good.

I had forgotten about that one. I copied both CDs to my hard drive.
The TR-7 Service manual is very well done, although he apparently didn't
"descreen" the photos, so they change quite a bit as you enlarge them.
All in all, a good choice. But if all you want is the TR-7, you can buy
a "real" original paper one for less than $80.

That may have been WB3CEZ. I think he used to offer printed, but it was
expensive to ship. Probably cheaper to take to FedEx Office and let
them print and bind it for what it costs to ship.

Another good one is from KE9PQ at
<http://auctionworks.com/StoreFrontProfiles/default.aspx?sfid=86409>.

He has a paper version for $20 that is also excellent quality.

About $400.00 to $500.00 for the L7 or L4B supply, they are the same.

3534. Small vs standard mic connector

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-04-26 17:59:46 UTC
From: Richard Knoppow
Topic: 3534 Message: 3534

Drake along with Collins and probably others use a small diameter RTS connector for the microphone. It has been suggested that this is to prevent damaging microphones by accidently connecting to the headphone output. Since my T4-XB has been modified with a standard 1/4" RTS connector I've given this some thought. I think the actual reason must be something else. The microphone is connected between the ring and sleeve, the tip being used for push-to-talk switching. So, assuming both have the same size connector, if a microphone is connected to a headphone jack it will not see anything because the ring will not be connected. It _is_ possible that headphones _might_ be damaged by being connected to some transmitters where there is sufficient current in the PTT circuit. In the Drake T4 the PTT is very high impedance and I think its unlikely that enough current could flow to cause any problems although the headphones would probably key the transmitter.
I think the real reason for the two different connectors may be an attempt at preventing errors in operating aircraft radios because interchanging the microphone and headphones would effectively disable communications. Aircraft have all sorts of safety precautions to make operation as fool-proof as possible and this may be one.
Another possibility is that the use of different connectors is to prevent problems from shorting the DC supply to carbon microphones. While these must be quite rare now the use of the small connector dates from a time when they were common. A standard headphone plug might short the mic supply to ground through the sleeve. Its possible, but not very likely, that such a short could damage the primary winding of the mic transformer, pretty much a necessity for a carbon microphone.
There may be a definite answer buried somewhere in the literature, these are just some random thoughts.

When I was in the USAF the headsets had PL-54/JK-26 connectors for the phones and a 2 pin connector for the mic. No way to screw up!

But I have not looked at an ART-13/BC-348 system in 50 years so I don't remember them.

Richard -

I believe you are correct in your deductions.... Most Avionics
equipment uses the different connector sizes, as does quite a bit of
more recent military gear. (Post WW-II)

Certainly there is potential for damage in certain cases, along with
keying the transmitter "accidently", but probably not many.

However, I suspect plugging a D-104 with a crystal element into the
audio output could quite likely damage the mic, probably before you
could turn down the gain. There are many other very expensive mics that
could be damaged in the same way. Yes, it would be harder to do if the
sizes were reversed, but the 1/4" jack and plug for audio output have
been around for 100 years or so and would be quite a conversion program!

Well, the point is that no audio would get to the mic
because its connected to the ring rather than the tip of the
plug. When an RTS plug is put into a tip-sleeve jack the
ring is not connected to anything. If a two conductor plug
is put into an RTS jack the ring contact in the jack is
usually grounded to the sleeve of the plug.
I am not sure how vulnerable the elements of crystal
mics are. Certainly crystal elements can be fractured by
over driving with an input voltage, my memory is that this
was a problem with crystal disc cutting heads so its quite

possible that a mic could be damaged this way. There are crystal headphones. Mostly they were made by Brush. The problem is that the crystals tend to become degraded with time and, eventually, they stop working. Rochelle salt crystals are vulnerable to moisture and high temperature. While most crystal elements were pretty well sealed they still do not seem to have survived well; its rare to find working crystal mics and phonograph pickups and Brush headphones. Brush headphones, BTW, are completely glued together so one can not even open them. A curiousity; they are marked on the outside that the patent notice is inside. You _can't_ get inside!

Uh-oh. So the mic element hits the PTT voltage as it's inserted. And somehow, I doubt that the PTT of the ART-13 is "low current" and/or "low voltage"!

The ART-13 is designed to use either a carbon mic(T-17) or a dynamic mic. I guess the dynamic mic can take the current.

The ART-13 has a switch to determine what type of mic is being used.

I just checked this out because the ART-13 was a Collins transmitter.

Lee -

Thanks, but I was complaining about the "Drakelist" @ zerobeat.net. It tends to get in "moods" sometimes, and just wondering if it's just me, or ...

DrakeRadio is working fine.

If the connector is the old phone company TRS and not a
modern "stereo" type the center pin will not contact the
ring contact because it is considerably smaller in diameter.
BTW pushing a stereo plug into a standard telco type TRS
connector may bend the contacts too much resulsing in
eventual failure. The telco type TRS are standard for
broadcast patchbay use.
Carbon mics may have supplies running anywere from
about 1.5V to around 6V. Less is better but the whole reason

for using carbon mics is that they are _amplifiers_ and have very high output compared to generator type microphones. The amount of amplification depends on the voltage across the mic. However, excessive voltage can cause overheating and fusing of the granuals and even arcing. Most applications have a fairly high resistance in series with the mic supply to limit the current.

I am somewhat amused by the thought that I built an adapter box with a .205
jack on it to adapt an aircraft headset to my TR-7.

WOrks great, BTW.

The three conductor .205", a.k.a PJ-068, that is the standard mic plug on the tube Drakes, which Richard was discussing. This is a Telex Airman 500 ANR headset for commercial aviation.

Anyone who has worked K0KKV on Field Day the past couple of years has heard it on the air (and will again this year).

Richard -

Very interesting..... I sent several replies over the last two days, and none of them "came back". I got a "Permanent Error" on each one saying that the message was refused and a "550 Authentication required" error. It just occurred to me to look at the Archives, and some of them actually got through TO the server, but still didn't make it back to me.

This reflector has these "fits" sometimes, so I guess I'll just wait it out. So far at least, when this has happened in the past it HAS eventually "recovered".

Beyond me but at least some of your posts seem to be
getting to the list.
I have a strange problem with mailing lists which are
on my dickburk address, which has a spam blocker on it. The
blocker puts all my posts into its "suspect" e-mail folder
but doesn't send me challenge messages. I have to move them
manually. This is evidently a bug in the software Earthlink
uses for its spam blocker and others have complained about
it but nothing has been done. Note that it does not stop
other posts from the same lists, just mine! The oldlens
account, which I use for the two Drake lists does not have
the tight spam blocker turned on (just "known spam") so
everything comes back normally. I don't use the oldlens
account on Usenet or the web, just a few friends have it and
a couple of mailing lists that won't accept address with
blockers so I don't get spam (yet).
BTW I also have an account at ARRL which reflects to

the oldlens account: WB6KBL@... Since its not
independent I am not sure what of what use it is.
At the moment I am listening to W1AW send code practice
on 20M. Steady as a rock. I have been working on my code
since I was about twelve. Faster than I used to be but not
up to where I want. I think it takes steady practice. I can
recognize some words and occasional phrases up to about 40
wpm but can't read reliably beyond about 20. I have the Koch
Trainer on this machine at work but there I listen to the
W1AW stuff off the web. An old friend, now dead, who was a
wireless pioneer told me about one of his friends who was a
commercial op. This fellow could take down high speed Morse
and talk to you at the same time. The code must of gone
right to his fingers, I doubt if he knew what he was
copying. I almost remember his name, I think he worked in
San Francisco for either RCA or MRT. My friend started with
the Robert Dollar line and Federal Radio and Telegraph and
eventually worked for Heintz & Kaufmann and later for Eimac.
He thought the world of Bill Eitel and thought Jack
McCollough was a first class bastard.
Anyway enough.

Pardon me, this was supposed to be a personal post to
Garey. Because the e-mail filters route everything with
certain headers into the list folders its hard to tell which
are personal and which are list. In any case, this was all
personal stuff and should not have gone to the list.

3557. FS Drake SPR-4

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-04-28 00:09:40 UTC
From: Saad Mahaini
Topic: 3506 Message: 3557

Hello, I have a real nice Drake SPR-4 that i decided to sell or trade. It's in excellent, original non modified condition. No flaws, no scratches, no dents, sparkling clean no corrosion chassis, super nice and works perfectly. Comes in the standard configuration with no additional options or extra rocks. $350 plus shipping and trades will be considered. I have a matching MS-4 speaker that i will offer the buyer for an additional $50 or will sell separately for $75 after the receiver sells. This is very well cared for receiver and its hard to find one in such condition. 73 Saad N5FF

Hi Everyone!

Free Delivery to 2010 Dayton Hamvention!

I'll be traveling from St. Louis, MO to Dayton Hamvention along I-70 and can deliver at no charge anywhere along that route or to the Hamvention itself.

I can't keep all the radios so I've decided to sell my Drake C-Line.

Included are the following.

* T-4XC transmitter with original (not a copy) Drake manual. Serial No. 21532.
* R-4C receiver with original (not a copy) Drake manual. Serial No. 18028. Receiver has the followng accessory filters: 6KHz AM, 500hz CW, and 250hz CW Filter. Also installed is a 39.1 accessory crystal for 28.0 - 28.5Mhz.
* AC-4 Power Supply for the T-4XC. Serial No. 42944
* MS-4 Speaker for the R-4C.

All the interconnecting cables (all are original Drake except for one). Price for all items as a package is $750.00 not including shipping or take advantage of free delivery to Dayton.

Here are photos:

http://www.mindspring.com/~vibroplex/drake_c_line.html

Terry -

I just checked, and actually it's only 32 Yahoo groups, all but two are radio and/or electronics related. Add to that two QTH "mailman" groups and a couple of "forum" memberships and you're approaching 40.

This list (DrakeRadio) seems to have more traffic lately, probably because others are having the same problem with Drakelist. There have been two posts today, and I responded, copying the OP of course, but neither of my messages made it to the list. I guess I'll just make this list my "home" list.

Don't know what causes it, but every so often Drakelist (or something along the way) refuses my posts and sends me a bounce message. I'm sure this is pretty far down the list of things Thom has to do, so it's just the way it is. I haven't changed ISP, email address, or anything else for over 10 years, and whatever it is has "cleared up" after a week or so the other 5-6 times it's happened in the last year.

I'm just tired of fooling with it.

Yes, it is for the Remote PTO, RV-3/4/4C. In the TR-3 ONLY, you need to jumper Pin 2 to Pin 8.

Pin 2 on the TR3's remote VFO 8 pin socket is connected to the TR3's VFO tube's cathode through the coil in T5.

Without the RV3 plugged into the remote VFO 8 pin socket, pin 2, the cathode of V2, must be grounded to pin 8 for the TR3's internal VFO to work.

When the RV3 is plugged into the TR3's remote VFO 8 pin socket and the RV3's Function switch is set to "OFF", pin 2 of the TR3's remote VFO socket is grounded. Placing the RV3's Function switch in other positions removes the ground on pin 2 except in the RV3's "RCV/XMT" Function switch position.

Bama has the RV4 schematic but not the RV3 manual or the schematic. However, mod.dk has the manual which includes the schematic.

I said,

"Placing the RV3's Function switch in other positions removes the ground on pin 2 except in the RV3's "RCV/XMT" Function switch position."

that's incorrect! Sorry about that, I misread the schematic.

What happens with the RV3 Function switch set to "RCV/XMT", the cathode of the RV3's VFO tube is grounded and the ground on the TR3's internal VFO tube's cathode that is connected to pin 2 is removed. This allows the RV3 to provide both transmit and receive VFO signals to the TR3 over pin 6 in the 8 pin socket.

Sorry for the incorrect statement.

David -

Drakelist has always been pretty good about that. It works very well,
when it works.

I responded to something there last night, and it went through! Just
takes "fits" now and then.

Guess I'll just stick around here for a while and see what happens.

Thanks Don,
I'm Dave w9ocm from Fairmount, IN (hometown of James Dean), with
nearly 50 years of hamming experience.
I do not currently own a Drake product but I joined this group in
hopes that I might find another TR-4 like I had before. (My wife keeps
asking me why I sell off the rigs I like - I don't have an answer.)
I've enjoyed the various topics for discussion that I've read here so far and am
looking forward to more.
The TR-4 that I owned a few years back had the smoothest VFO control
of any transceiver I have ever used.
I did some DX work with it and maybe again one day, eh?
One question - if I were to consider a Drake receiver, to match up with
a Ranger xmtr, what would be some recommendations? And why? Lots
of changes here at this QTH since Social Security became part of my life.
Have a fine afternoon.
Dave w9ocm

I don't know the best way but I just tried this with a
"carbon" pencil. It works, makes a nice dark mark which
comes off with a standard eraser or window cleaner. The
particular pencil I used is a General's Carbo-Weld Black
Marker. I think a Wolf's Carbon Pencil, available at art
supply stores would also work. These pencils do not have a
sheen on the marks and are darker than normal writing
pencils, even very soft ones. I don't think a permanent
marker or decals should be used because you might want to
get the marks off again. I don't know what sort of plastic
is used for the dial. It stands up to window cleaner and
"Fantastic" but might not to some more powerful solvent.
That's why I would not use a "Sharpie" or similar marker on
it. Others may well have better ideas.

From: Garey Barrell
Topic: 206 Message: 3582

Hi Dave -

Welcome to the group. I used to hang out over on Drakelist, but for some reason every so often I am unable to post there. Pops up every month or so, and lasts for a "while". So I gave up. :-)

Don started this list about 5 years ago, and when he moved on to other interests he asked me to take ownership of the group.

I guess the first question would be do you intend to operate CW or AM with the Ranger/Drake combination? Should the answer be "CW Only", (my preference!,) the 2-B would be great, although it IS a little dwarfed by the Ranger. Any of the R-4/A/B would be a little better, adding 1 kHz dial calibration, crystal calibrator, and even transceive capability with the T-4X(any) transmitters.

The maximum IF bandwidth of the 2-B is 3.6 kHz, a little narrow for AM unless you want to use ECSS, which kind of begs the question of "why AM"! The 4 Series receivers have a 4.8 kHz bandwidth, which is a little better, but still kind of pinched for AM.

The R-4C has an 8 kHz "roofing" filter, and combined with a bypass for the optional AM (6 or 8 kHz) crystal filter does fairly well. Unfortunately, the R-4C audio leaves a little to be desired, which again begs that question.....

My personal opinion is that the R-4B is the epitome of Drake receivers for just day-to-day operating. It has the Passband Tuner L/C IF filters which I prefer over the crystal filters in the R-4C, unless you are trying to dig out a weak signal amidst a pile of 40 dB over S-9 signals. This used to be important, but nowadays the only time you find that kind of situation is trying to pull a DX station out from all the "policemen", or a Low Band contest.

The R-4B has smooth audio you can listen to all day without fatigue, thanks in part to the lack of steep crystal filter skirts, plus you can hear what's going on around your frequency, just at reduced levels.

On the other hand, it's hard to beat an HQ-129X, HQ-140X, NC-300 or 75A-2 for just good, solid AM! :-)

Black-on-clear P-Touch labels work well. You can pick your font size and trim them to fit, and they look good.

Hi Bob -

The 75A-3 has the mechanical filter, (3 kHz,) which to me makes it unsuitable for AM. A "real" AM signal needs at least 6 kHz to be worthwhile, if you're only going to listen to one sideband and restrict it at that, you may as well use SSB! :-) Even without the mechanical filter, the IF bandwidth of the A-3 is too narrow for good AM.

You just haven't heard AM until you hear it on one of the receivers I mentioned earlier.! Preferably with a 10" or larger speaker in a good case. There are other good AM receivers, just about any of the old Hammarlunds or Nationals, or even Hallicrafter's SX-99. The SX-100 was a little too narrow for great AM.

SSB is definitely superior for _communication_ , i.e., carrying information from one place to another, especially under crowded conditions, but "being in the room" with someone takes AM! :-)

Best of all is an old Hammarlund Super-Pro. These have
a variable IF bandpass which is about 15 khz at maximum, a
low distortion detector and relatively high fidelity

push-pull audio. The IF transformers use a sliding coil arrangement to vary the coupling and thus the bandwidth. They also have an excellent crystal filter for CW and isolated AVC so that the BFO does not show up in the AVC. The later SP-600-JX also has a pretty wide maximum IF, about 13 khz. The audio amp is the usual single-ended job found in most communication receivers but there is a direct detector output which will amaze you when connected to a good audio system.
A few receivers have over coupled IFs that require tuning with a sweeper. The HQ-100/120/140 series have this arrangement as does the RCA-88A/C series. In fact, I think the Collins 75A has a similar arrangement. If just peaked the bandwidth is narrower but the skirt selectivty is lost. The bandwidth across a properly tuned IF is about 4.5 to 5 khz. Not exactly hi-fi for AM but enough. Also, the Hallicrafters SX-28 and SX-25 have variable IFs and push-pull audio but are not quite in the same class with the old Super-Pro.
I have a beef with AM radio broadcasting. Its _capable_ of quite high quality if not full high fidelity. In the bad old days stations tried to sound as good as possible, now they just want to sound loud. Modern transmitters are much better than the old ones were but the processors that feed them are just awful and no one in the business seems to realize that bad audio chases listeners away. You can always tell when sweeps week comes because all the AM stations crank everything up and sound even more awful than usual. Even a five tube wonder will sound pretty good when fed with a clean signal.

3589. FS: 2LF 160M converter for Drake 2B or 2A

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-05-03 04:08:39 UTC
From: mecograph
Topic: 3589 Message: 3589

Hi Everyone,

I have a 2LF for the Drake 2B or 2A. I don't have either of those receivers so I can't test it. It is missing a crystal so you would need to buy one of those to make this work. Here are a few photos:

http://www.railroadmorse.com/2lf%20004.jpg

http://www.railroadmorse.com/2lf%20003.jpg

http://www.railroadmorse.com/2lf.jpg

Price is USD$75.00 plus shipping which should only be a few bucks because of the small size. I'll be coming to the Dayton Hamvention this year and I can bring it with me to save shipping expense if you like.

Thanks and 73,

Derek

Hi Martin -

The Drake 4 Line transmitters all require a higher GAIN setting for CW, sometimes over to 3 or 4 O'clock or almost full clockwise. It will be advanced further on the higher bands, and does vary from band to band. Very high settings are sometimes the result of weak tubes, especially V2-V4 and V5 and V6.

R25 blowing is a sign of a short on V2, Pin 5 (result of an internal short from Plate to Suppressor grid inside the tube), or sometimes a short INSIDE T2. Possibly a shorted C20, but that is way down the list of likely causes. I would first check the transformer lead that R25 connects to (with R25 OUT) to ground with an ohmmeter. IF very low resistance (or short), then remove V2 and recheck. If OK, the problem was a shorted tube. IF still shorted, it's probably inside T2.

If the tube is at fault, T2 may have been damaged (overheated) and will need to be replaced. If the short was on the "high" (R25) side of T2, the transformer is probably still ok. If on the "low" side (V2, Pin 5) T2 has probably been damaged.

Let us know what you find.

Tnx Gary for your answer,

The gain was full clockwise cw position. Always same erratic problem ... full output on tune and 25 watts on cw position.

Rapidly this afternoon i used radio agn and on tune position radio was right.

Further information later.

Agn very tnx for your help. I changed the dirver for a new one and finals seems ok. I will change other suggested tubes.

TNX tnx and best 73 Gary

I made a mistake, to nite i checked agn the radio and NO output on CW or Tune position with R25 blow.

I checked OHM between Pin5 of V2 and R25 and there is 3 ohms. With or without V2.

I put a new resistance and new V2 and no output and no smoke !!!

I can try new V5 and V6.

I hope it can help.

From: mfelack
Topic: 3596 Message: 3596

Hi Group!!!
I recently acquired an average quality MS7 from eBay that sounds terrible on my TR7 - like the speaker is "blown" - all distorted and scratchy. Do any of you Drake enthusiasts know of a suitable replacement (hopefully better than OEM version that it came with) to install in its place to make it functional again or perhaps even better than new? Also, does anyone know what the actual hole spacing is for the mounting screws?

Martin -

If R25 is blown, then there is a reason in the V2 stage. Most likely is
a shorted tube. I would be careful using it until you replace V2, as
damage to T2 is quite possible IF it is in fact the tube. Something is
drawing excessive current if R25 is blown!

OK. Seems most likely that the old tube was shorted, Pin 5 to Pin 2.
It may or may not show with an ohmmeter check with the tube cold.

I can't say for certain, but I believe that the T2 is identical in both
the T-4XB and T-4XC. They both have the same internal cap, and the same
circuit topology. It tunes to 5.645 MHz in both units and the output
link matches to the same crystal filters.

When you get the old one out, open it up and inspect it for damage.

There is nothing in the TR-4 that would help, as it is an entirely
different IF.

Hello Gary

just before leaving home this morning i used the T4XC.

New V2 and i have got 5 watts output on 40 meters.

Gain pot half and i tried full and no difference.

I am not very enthusiastic to change T2 ...

I am wondering if there another possibility ????

Another thing to check before T2 job ...

Tnx agn Gary

Yes, changing T2 is not a pleasant task, although there are worse ones! :-)

I would tune the transmitter, switch to CW, and adjust the core in T2.
It should have an obvious peak very close to where it is currently set.
If it DOES peak, we may have to look elsewhere. If it does NOT peak,
then I think changing T2 is the task.

If you have an oscilloscope, in TUNE mode you should see about 200 mV
p-p on the Grid (Pin 1, V2) and about 6V p-p on the Plate (Pin 5, V2).
You'll probably have to increase the GAIN to compensate for loading of
the scope. You should have about 2V p-p on the Secondary of T2.

So whats the best method to change the meter light in the TX4B? I see the lights are in series to when one goes they both go. The meter light bulb is really in there tight...is there a secret to easy changing it?

Thanks for any replies

de Tim KØFL

Tim -

I usually use a small screwdriver and pry the meter light clip against whatever is close to work it off. Once you get it started, you can insert your tool in the bend of the clip to pry it the rest of the way off.

I would replace both bulbs with #755 bulbs, and you probably won't have to do this again. The #47 is rated for 2-3000 hours of life and the #755 is rated at 20,000 hours.

When you replace the bulb, be sure and orient the lugs on the back of the socket so they aren't near the bracket or housing. They will turn, and if there is tension on the wires it can pull them into contact with the chassis, resulting in a blown bulb, or filament fuse.

Date: 2010-05-04 15:38:45 UTC
From: Tim Randa
Topic: 3601 Message: 3603

Hi Garey and thanks for the advice. I couldn't get the clip to break loose from the bracket so I went ahead and removed the front panel to be able to loosen the meter and get to the bulb. Wasn't hard be there had to be a better way. I broke loose the bulb clip when I had access so next time will be easier. I am a new owner to the B's and so far really like the station. One thing I notice is I have a 50 watt difference between using the TX or the RX for transceive operation. What might I look at to resolve this?

Thanks again

OK. Sounds like T2 is ok, good. There just aren't many things that could cause R25 to burn. It appears that it was probably a shorted 12BA6 in V2.

Since you did not comment, I assume you do not have access to an oscilloscope. That makes it a little tougher.

Have you tried a new, known good V1? 12AX7A

Check the value of R28. 220 ohms

Check the DC voltages on V2, V3 and V4. Tune up the transmitter on a dummy load on 40M. Leave the unit in TUNE, and reduce GAIN to minimum and measure the voltages on this three stages.

Hello Gary

Yesterday was very encouraging for my T4XC.

R26 burned, pin 6 of V2 short to ground.

Now T4XC transmit.

On 15 and 10 meters need more gain. Pot is full butit is not enough. I have 75 watts on 21 but on tune position. 5 on cw position.

I will check frequency in carr osc jack with my frequency meter.

OK. Probably what happened was that the Plate of V2 shorted to the Suppressor, burning R25, and when Plate voltage was lost the Screen began trying to take its place. That caused the Screen to short to the suppressor also, taking out R25. So almost certainly a bad V2 started the whole thing.

The Car Osc frequency should be near 5.644999 MHz in CW, and shift up about 800-900 Hz in CW. Check value and condition of R104.

Topic: 3613 Message: 3613

I was just given a complete Drake system, including AC-4 and MN-4 tuner and D-104, non-amplified mic.

The transmitter is a T-4X....It doesn't have the 'moguled' knobs my B has....but other than that, what IS the difference between the older transmitter and the B??

BTW...the copper on this one is pristine, only one little blemish on the T-4X and none on the R-4B.

I was helping an older lady (One of my wife's patients) move to an assisted living facility...and she had this radio wrapped in big garbage bags in one of closets. It belonged to her late husband who passed away 30 years ago. I looked at the radio and told her she had a 'barn find' in her closet...I told her I would try and sell it for her.....she asked if I had any use for it....get that? Use for it??!! I told her yes but it was worth some money and she should try and sell it...she said, "No, just take it...thanks for helping an old lady move."

How could I be so lucky a second time! My first B line came to me in pristine condition, cosmetically, as well. Oh well, I didn't win anything at our Emcomm raffle here in Reno last week, so this was my raffle prize.

Ahem....Still looking for an L-4B.....thank you very much!

Hi Joe -

I've been doing this stuff for 50 years, and I've NEVER fallen into one like that! :-) Obviously I've picked the wrong old ladies to help!!

Other than a few cosmetic differences, black lettering about the "belt line", "PTO in use" light, dished dial skirt, and removal of the five kHz dial marks, they are essentially identical.

The only significant difference between the T-4X and the "B" is that the former has four pole crystal filters and the latter has six pole filters.

As a result, the T-4X is marginal at best on SSB for Carrier and unwanted sideband suppression, by today's standards. The only caveat I would suggest is to not drive an L-4B, (or any other,) linear with it on SSB. It's fine for CW, but for SSB I'd stick to barefoot operation, especially if you have any nearby Ham "friends"!

Joe,

I have a spare L4B for sale for $800 plus shipping. It works great and is currently wired into the operating position in case you would like to hear it "live". Tubes are in great shape and as far as I can tell it works perfectly. Cosmetically it looks excellent. I'm selling it only because I acquired a virtually brand new L4B with new tubes and am rebuilding the power supply with Mike Bryce's board. Don't need two!

Hi George.....

Sorta sounds like a dumb question, but the L4B you have...that does or does not include the power supply. Your message sounds a bit like you are rebuilding that P/S for the new(er) L4B.

If it does include the P/S, I would be interested. 4 call. Virginia? Your call is very familiar....I think I wrote you a while back....you have labs, if memory serves.....I mentioned that my oldest son has a red lab, I think it is....good bird dog...took to upland game birds with no problem. (Quail, chukkar, pheasant, grouse, sage hen, etc.)

I wander from the subject...if you have pictures, in and out, I would be delighted to view them.....my Gmail address accepts large files so you could send them to me there.

Fellow Drake Enthusiasts,

The Drake Forum Committee would like to invite you and welcome you to the Drake Forum and the Dayton Hamvention. The Forum is on Saturday of Hamvention weekend, next weekend, at 10:30 to 11:30, in Room 2. Featured speaker is Rob Sherwood, and there is a free raffle. More details are on the DARA website.

Informal gatherings of Drake Enthusiasts can be found throughout the weekend at the fleamarket spaces for Jeff, WA8SAJ, one of the net controllers for the Drake Technical Net. His space numbers are 2328, 2329, and 2330. Be sure to stop by and say hello. Take a look at what he has for sale too, you might just find what you need.

Safe travel and welcome to Dayton!

Evan, K9SQG

From: arsnf7z
Topic: 3626 Message: 3626

funny, it never seemed much of an issue when I used my Drake equipment in the 1970's. fast forward thirty years, and spoiled by newer Icom transceivers with 1-hertz tuning, and my Drake PTO seems way too coarse. that is, I'm always wishing for another 2:1 reduction. anyone else notice this? it seems the tuning is, for me, right on the ragged edge of being acceptable for sideband signals. I'm adjusting, slowly, but it did occur to me that the ratios aren't optimized for SSB. are the Collins PTO's about the same tuning rate per dial revolution?

is it just me?

Daniel -

All I can say is that 'way back then' nobody was concerned whether they were on 14.175000 or 14.175100 kHz. :-)

There seems to be an increasing "need" to be on an "even" kHz, or 10 kHz, etc. We're becoming channelized!! It's not nearly as bad on CW as it is on SSB, perhaps it's the influx of CB operators who are used to channels?

Personally, I, like MANY others, developed a "safe-cracker's touch" from using receivers with dials that covered the entire 50 kHz wide Novice CW band on less than one fourth of a 1 kHz division on the Drake. Seriously... :-)

All that aside, the Drake PTO is 25 kHz per revolution, and the Collins S-Line is 20 kHz per revolution. So if you really NEED that degree of control, aside from buying one of the new $5000 + transceivers with 1 Hz synthesizer steps, you might want to work on your "touch"!! :-)

I'm with Garey on this. All you need is a fine touch and a little patience. I always thought the "modern" radios with 100 Hz or smaller tuning steps tune too slowly. Even mobil with my HR-2510, I usually go in 1 KHz steps and make up the difference with the variable knob formerly known as "RIT".

I'll take any analog VFO any day over a digital gadget, because you can never seem to get right.on.the.other.guy's.frequency with digital stepped tuning.

Hi Garey,

Recently you kindly replied to my inquiry about the TR-4C tuning gears. The gear seems to have loosened up and doesn't stick on the shaft anymore :)

However, I have noticed what seems to be a bit of clutch slipping. Is there anyway to fix this ?

I feel like I'm really close to getting the TR-4C back on the air.

Next up on my fix list:

RV-4C
R-4A
TR-3 with a very strange problem.

thanks,

Bill

Thanks,

Bill

Bill -

The "clutch" is just behind the dial plate behind the MAIN TUNING knob. If you remove the knob and plate, you'll find a (probably gray) piece of plastic/rubber tubing slipped over the shaft. It's 3/8" o.d., 1/4" i.d., and a little over 1/2" long. Over time, this material gets hard and the ends become "polished" and slip against the back of the metal dial plate.

First step is to replace the knob and plate, and press in on the knob towards the panel while tightening the knob setscrew, essentially compressing the clutch. If it still slips, you can "sand" the ends to roughen them up a bit and try again. Still no luck, then see what kind of tubing you can find. I have used the clear poly tubing from the hardware store rack, (you get funny looks when you ask for 1' of tubing,) rubber surgical tubing, and some have used automotive "heater" hose, the stuff with the re-inforcing threads in it.

In all cases, press in on the knob while you tighten the setscrew to engage the friction clutch.

Let us know!

I think my 'touch' is just fine. I too grew up with a BC-348, Arc-5's, and other less refined receivers, and never had a problem. of course, they generally all had BFO controls or some other form of RIT. my question is as an engineer, and has nothing to do with finesse. my point is, is that touch or no-touch, the tuning-rate could benefit from a slight reduction as with Collins. it's a personal preference, most certainly, and I would have designed it slightly slower.

I have no issues with digital tuning. the channelization is a simple artifact of synthesized tuning and is a benefit. my complaint is the implementation. I dislike having to enter a menu to change the tuning rate, but do appreciate the precision and stability of my Icom 7000. the Drake tuning rate is fine for AM and CW, and acceptable for SSB, but not optimum in my opinion.

I wonder if some sort of slow-motion drive, a'la the
75A4 could be devised. I don't know the details of the
Collins arrangement but the first receivers did not have it.
I think it may be no more than a ball-bearing speed reducer
as part of the tuning knob. Not sure if this could be
implimented on a Drake receiver easily, but perhaps someone
with more knowledge of these things could tell us if its
practical. I am able to tune SSB satisfactorily with my R-4B
but then I am somewhat old-fashioned.

Richard -

Surely, as an "engineer" who's "touch" is "just fine", he should be able to devise such a mechanism! :-)

I envision a bracket bolted to the table in front of the receiver with a ball reduction drive mounted on it, and an eight inch diameter knob on it! :-)

Another layer of skin might help too!

Actually, the Collins 4:1 knob is what I believe is called a cyclical drive, or possibly ring and pinion. NO "stinkin' " ball drive for Collins. See attached photos. It was a $29.95 option on the 75A-4 in the 50's, but this is a repro, and cost more than an R-4B today! :-)

Yes, YOU can tune SSB, _BUT_ can you set your receiver to 14.175000, huh!?!?!?!? Can you!?!?!??!

Different strokes for different folks, I guess. :) I find the Drake tuning to be a good middle ground between band surfing and gnat's-behind nailing. Slow tuning rates annoy me, but that's just me. I think Garey and I could find each other on HF SSB just fine.

Wow.

This isn't April, so those pics must be real.

Would be much simpler to build one of those nifty DDS VFOs, then he could microhertz to his heart's content.

3636. Re: TR-4C clutch slipping

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-05-14 05:21:45 UTC
From: wa6neq
Topic: 3626 Message: 3636

Garey,

Took off the knob and skirt and the grey plastic "clutch". Ran it over a sanding block for a few short passes just to roughen the ends without removing much material. Put it back together wi5th some pressure on the knobs. Reset the dials to read the proper frequency. Now it tracks pretty well from 0 to 500KHz.

I need to do the same with the RV-4C, too.

Thanks for the help,

Bill

3637. FS RV-4 serial number 15039 (early 1973) Two-Tube version Silver trim

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-05-14 10:29:43 UTC
From: Kris Merschrod
Topic: 3626 Message: 3637

This is a nice Drake assesory - provides a speaker, and a place for the AC-3 or AC-4 plus allows split operating for the TR-3 or TR-4 lines.

I have for sale this early RV-4, Two Tube version (OA2 and 12AU7) Later models were single tube). Face plate is very clean (has the silver trim around the perimeter), the cabinet is dull and scuffed in places. The chassis (copper plated) has the usual "freckles" and underneat in one corner it is "rusted." I have tried to use it with my late model TR-4CWx and it only works in one position and I can't figure out why.

Although I have the original speaker (it was buzzing) and will include it, I have installed a new 4 ohm speaker.

Who will give me $125 for it?

funny -

there is a difference between using a tool, and suggesting that the tool could be refined. I was really just contributing a post/topic to liven up an abeyant forum. I don't hold such an allegiance to Drake, to not recognize and suggest areas of improvement. I still think the tuning rate is slightly too fast for a receiver without some form of RIT.

no problem though, hearing from others with a differing opinion. one persons complaint is anothers feature ... if I want to operate exactly on 14.175000 Mhz I'd use my Agilent 33220A Arbitrary Waveform Generator as the Injection source. or use my Icom :)

or possibly, I could build a stepper-motor and belt drive to the main tuning knob and do it 'old tech'. or maybe my tuning 'touch' is sub-par and I can take a workshop.

just a bit of levity ... like I said, the forum was quiescent. my next topic will be critical of the RCA phono connectors used or the 'less-than-optimum' product-detectors. there is room for improvements. good topics for a forum about Drake radios methinks <grin>

Absolutely! Please don't let the "humor" here put you off..... I
guess for some it's a little too pointed.

I like the "stepper-motor and belt drive" idea.! There was a similar
approach taken many years ago to scan the six meter band on a Collins
75A-4 with a converter in front of it. I believe it may even have been
a cover article! Would certainly touch a nerve with the Collins guys
today, although it was considered "innovative" at the time.... :-)

I'm looking forward to your next topic!

A long time ago I saw a picture of a receiver at
coastal telegraph station KLC in Galveston set up for
automatic scanning. It was a WW-2 vintage Super-Pro with a
motor drive attached to the band spread shaft. I never saw
any details of how it was rigged.

to be fair .. I think the Drake tuning rate is only marginally fast. I think the 20khz rate cited for the Collins PTO would be perfect. no need for anything slower than that.

the RCA phono jacks are a strange choice, until you look at the costs and the fact that we're operating at relatively low frequencies. I've own seven Drake pieces, with a mint TR4XC and R4C sitting here on my sailboat, and when I had an engineering lab available I did some studies and couldn't really justify changing to BNC. I think I did change RCVR input on my R4B to BNC .. but there is little need to do so. this week I finally bought a T4XC, so the phono plug makes sense when used with a companion Drake. those RCA/SO-239 adapters are evil!

I never liked the SSB audio on my Drake R4B. so, it wasn't long before I bought the R4C which to my ears, sounded much better. oddly enough, the word on the street is that the R4C product detector is inferior to the R4B, but I sure didn't see it that way. I also hear reports of the 'stunning' audio on the R4C, and wonder if everyone knows it is a solid-state audio amplifier. even the TR4XC has a solid-state buffer/pre-amp, though it does drive a bona-fide tube output stage. AM sounds great on both!

I love Drake equipment and its design. I'm having a blast using equipment that has tubes and big knobs. heck, I just ordered a 100th Anniversary Vibroplex Original Bug .. just to keep the mood going. no lava lamps though .. yet :)

sorry ... I meant to say TR4C and not TR4XC.

anyone, sell me your RV4C!

one more point. I just bought this mint TR4C, and the previous owner had swapped out the original speaker for a Jensen speaker with a 10oz voice coil. it sounds soooooo good. just the right added response on the low end to add ooomph to most signals. not optimized for DX, but it really does bring a new dimension to many signals. I just bought another MS-4 and since I am partial to Alpine speakers, I am wondering about the experience of others that have found a great replacement for the MS-4.

I am up against a real obstacle. I live on a sailboat. a large sailboat, but nonetheless, one that doesn't come with a 110 VAC source. my latest foray into restoring Drake equipment has left me with the harsh awareness that DC/AC inverters are horrendously noisey. in fact, they are useless. so much has is generated that I cannot use the Drakes on the boat. one partial solution, is to bypass the inverter on the boat, and generate 110 VAC with my Honda generator. it's better .. but now I have ignition noise, and still, RFI that is unacceptable. ok above 10 Mhz, but wipes out 80 and 40 meters.

I've been looking for a smallish, 600-1000 watt inverter that is relatively shielded and quiet. it occurred to me that those that work Field Day may have been up against this same problem. anyone discover a DC/AC inverter that is relatively noise-free on 4 Mhz?

yes, I know .. why the heck are you using tube rigs on a sailboat? like I mentioned previously, ham radio lacked lustre with the new rigs. no uncertainty! there was something missing, that I used to love when I used older equipment. same with electronic keyers. sure, I can send faster and more accurately with an iambic keyer, but I missed hearing a signal and being able to identify the station from the operator's fist (and clicks/chirp). so, I bought a new Vibroplex bug. talk about personality! I have a couple of Icoms on the boat, but ho-hum. I missed dipping plate-current and a real 'loading' control!

anyone?

I think what you need is something like a pure sine wave inverter. The stepped sine wave inverters generate RFI. See:

http://www.theinverterstore.com/the-inverter-store-category.php?cat=PSW

for some examples.

Do you use the backstay for an antenna?

Two thoughts:

1) Get another Honda generator (or similar) with a scrap engine. Replace it with a suitable DC motor & arrange feedback to the motor to maintain the 60Hz.

2) How about a 60Hz osc driving a modern Class-D amplifier? I believe they're super-efficient these days (& big, too).

I live on a sailboat. a large sailboat, but nonetheless, one that doesn't come with a 110 VAC source. my latest foray into restoring Drake equipment has left me with the harsh awareness that DC/AC inverters are horrendously noisey. in fact, they are useless. so much has is generated that I cannot use the Drakes on the boat. one partial solution, is to bypass the inverter on the boat, and generate 110 VAC with my Honda generator. it's better .. but now I have ignition noise, and still, RFI that is unacceptable. ok above 10 Mhz, but wipes out 80 and 40 meters.
>
> I've been looking for a smallish, 600-1000 watt inverter that is relatively shielded and quiet. it occurred to me that those that work Field Day may have been up against this same problem. anyone discover a DC/AC inverter that is relatively noise-free on 4 Mhz?
>
> yes, I know .. why the heck are you using tube rigs on a sailboat? like I mentioned previously, ham radio lacked lustre with the new rigs. no uncertainty! there was something missing, that I used to love when I used older equipment. same with electronic keyers. sure, I can send faster and more accurately with an iambic keyer, but I missed hearing a signal and being able to identify the station from the operator's fist (and clicks/chirp). so, I bought a new Vibroplex bug. talk about personality! I have a couple of Icoms on the boat, but ho-hum. I missed dipping plate-current and a real 'loading' control!

my wife loves me dearly .. but I am afraid that if I suggested she hand-crank a generator during my QSO's there would be serious problems with my marriage!

yes, it has to be a pure sine-wave generator. anything else will make the iron in the transformers quiver till they fail. the marine inverters are pure-sine, and you have to pay extra for a pure-sine small inverter. no problem .. I just want to fine one that is adequately shielded and doesn't emit DC-to-Daylight hash. so far, it's no go. the Drakes, my R4C and TR4C outperform my IC-7000 (except for selectivity) but to power them, I need to generate 110 VAC and the insuing noise blankets 80-meters. dang!

so, my search is for a very low noise inverter, pure-sinewave, and relatively cheap. I have Xantrex inverters on the boat, but I need something more refined in terms of RFI. the Honda generator comes close, and I might be able to replace the spark-plug with a resistor-plug and do some shielding. I was hoping to find Field Day addicts that have been up against the same problems and have found a solution.

still looking for a MN-2000 and L4-B ... who isn't!

Can't you replace the Drake power supply with a DC-DC one made for mobile
use? Then, all you need is a hefty 12V battery or three, perhaps even
solar charged.

Daniel -

Have you considered the Drake DC-4? It's designed to power the TR-4C or
T-4XC plus a 130 VAC outlet for an R-4C.

There's one on eBay right now with at $0.99 with no bids.

Not gonna drive the L-4B tho.....

Gary,

it's a very good suggestion. it won't power up the R4C, but I can easily craft a solution I suppose. and, I think the Drake DC/AC inverters are scarce and expensive. I use an isolated backstay, that helps hold my mast up, and a Icom AT-140 tuner. I use the Icom-7000 to tune the antenna, and then swap the antenna to the Drake. unfortunately, the noise generated by my means of generating 110 VAC almost blankets the receiver. boo hoo .. when I am in the marina, I have access to clean 110 VAC, but the noise generated from 1000 boats and the University of Washington Marine Science Lab .. is worse than my Honda generator.

3656. DRAKE TR4-C Potentiometer

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-05-15 09:00:13 UTC
From: radiomilitary
Topic: 3656 Message: 3656

Hi, Hall

The potentiometer (RCVR / RF + SW) of my TR4-c is not ok.
help me, which are the characteristics of the 2 sections, on schematic
the value are (For RF GAIN 10K and RCVR GAIN 500K)
Question : Linear o Logarit.

Where I can acquire something of similar or to assemble an different model.
thank you for all
Frank

3657. Re: [DrakeRadio] DRAKE TR4-C Potentiometer

Frank -

The 500k rear section is an "Audio" (log) taper and the 10k front
section is "Linear". The switch is rated at 6 A @ 120 VAC.

Aside from a replacement from a "donor" unit, the best chance is to find
single potentiometers from the original manufacturer (CTS in most cases)
and 'transplant' just the resistive wafers to the old mechanism.

is shown as a stocking distributor for CTS products. I would call and speak to an applications engineer, and explain your problem.

You should check the potentiometer in your radio to be sure it IS CTS, most are, but not all.

It would also be worthwhile to post a request on the list(s) to see if perhaps someone has one from a junker radio.

3660. Re: [DrakeRadio] Re: Drake PTO tuning rate ..

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-05-15 22:15:17 UTC
From: William Houghton
Topic: 3626 Message: 3660

We could mechanically couple the tuning shaft to a DC motor fitted with an optical shaft encoder such as the HP HEDS series. Connect that to an LM629 PID controller (provides both PWM drive and encoder position sensing). Connect that to a microcontroller. Buffer the PTO output and feed that to a counter of the MCU to measure the PTO frequency. Add a display and keypad. Write some embedded firmware and you could probably get tuning that matches today's rigs.

Absolutely! Please don't let the "humor" here put you off..... I guess for some it's a little too pointed.

I like the "stepper-motor and belt drive" idea.! There was a similar approach taken many years ago to scan the six meter band on a Collins 75A-4 with a converter in front of it. I believe it may even have been a cover article! Would certainly touch a nerve with the Collins guys today, although it was considered "innovative" at the time.... :-)

I'm looking forward to your next topic!

My background is in microcontroller applications. I've done a lot of PID motor control using the LM629 in the stage lighting industry, mostly for major rock-n-roll groups. For this application we could probably eliminate the PID portion of it. Since I was laid off a few weeks ago, I probably have time to try it !

As a product opportunity? How many people buy an old tube rig and expect to be able to tune the frequency like a modern radio ? I do have to say that from what I have heard on the bands, people seem to be a lot pickier about being exactly on frequency these days. (I think the real reason for RIT was for round tables on SSB).

OK, since we are going all out... I suppose it would
be possible to modifiy a Drake transmitter and receiver to
work from an external frequency synthesizer. For maximum
stability and accuracy the synthesizer should be locked to a
GPS satellite or, perhaps, a local atomic standard. All this
is not quite as far-fetched as it might seem.
OTOH, I suspect that if one knew how the PTO's were set
up at the factory it would be possible to improve the
accuracy of the dials by choosing the various fixed trimmer
or padder caps correctly. I wonder if anyone has tried this,
I am not quite curious enough to have at it.

There were several "ladies" at Drake who did the linearization and temperature compensation on all the PTOs. They were the ONLY ones who knew how to do it! I believe it was Bill Frost who told me that they would sit and talk about their Grandchildren and wave their hands over PTOs all day. There are NO trimmers, only selected ceramic caps, about 3-6 of them in various PTOs. If you open one up, there are caps in some places, none in others, and some tapped halfway up a bus-wire lead. I don't know of anyone who has made one "better"! :-) I have changed

FETs in a couple with no apparent effect on either linearity or tempco, so the compensation is probably almost all coil dependent. I also heard that the coils were wound, coated and baked for several hours prior to assembly.

Enough that there are probably at least three (that I know of) fellows making
add-on DDS VFO units for sale to hams.

I have heard two similar stories: One is about the
eight gang tuning capacitors used in the Hammarlund
SP-600-JX. The stators are held on by three clamp screws and
must be aligned to the rotor. The story is that there were a
couple of three ladies at the plant who adjusted all of
them. AFAIK, no procedure exists but the requirements are
such that they can be aligned mechanically. BTW, NEVER bend
any capacitor plates on these things.
The other story is aout a small group of ladies who
loaded film packs at Kodak. Film packs have been gone long
enough now that I imagine many people don't know what they
were. A film pack was a package of anywhere up to eighteen
sheets of film in a holder that fit in a simple adaptor for

cameras that were designed for sheet film or glass plates.
The films were changed by pulling a paper tab on the side.
After exposing the picture the tab for that sheet was pulled
out which pulled the sheet around to the back of the holder
leaving a fresh sheet on top. The film was very thin similar
to roll film. I don't remember when the last ones were made,
I think about twenty-five years ago. One story is that the
last of the ladies retired and no one was left who knew how
to assemble them. Of course the truth is probably more
likely that sales fell off so the product was discontinued.
Setting up a Drake PTO sounds like a not impossible
but likely very tedious job. Adjusting temperature
compensation would be a bear since the things would have to
be tested over whatever temperature range is required and
some sort of record kept of the result. The PTOs in my Drake
4B twins do not seem to drift at all so evidently this job
was done well.

In 1966 I had a business trip to Collin's in Cedar Rapids. While I was there
I was introduced to the tech that aligned ALL Collin's PTOs. He was blind.
He used a wheel on the shaft with holes in he could feel for positioning. He
listened to the beat note with a reference oscillator. He adjusted the
tracking by tweaking the coil in each position of the wheel.

3672. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-05-16 20:36:57 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 3672

All group memebers are welcome to post here on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others (what you put into this group you will get back so participate if you have a chance). Although we would like to focus on Drake Radio subject matter any Ham Radio subject matter is allowed. This includes any QST's of events or hamfests, especially if Drake radios are included

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our groups home page, as well as links to Drake information or your homepage.
Thanks to all members for your particapation.

Don

Ok Don, I guess I'll jump in feet first. This is Tim in Wichita, Ks. I recently acquired a set of B-Line Twins and have been having fun despite the band conditions. I have a set of inj cables in route that I should receive Monday and hope to give an alignment to the receiver a try. One of my question is...is the information in the manual enough to complete a good alignment or is there info in a service manual I should also have? I gotten some good emails and advice from some members on this group already and look forward to reading the list in the future.

I assume there is a Drake users net...freq and time would be good to know.

I'm generally a lurker. Licensed since 1961 (50 years this next April), I
have
enjoyed many different aspects of ham radio.
My best contact thus far is the Amundsen-Scott South Pole Station in 2001.
I just got the winning bid of an original Drake TR-4 manual off eBay. It
should
be here soon. I'll have the manual; next I'm looking to get a really nice
TR-4
(again) as soon as I can part with some equipment.
I have to sell some because SS checks don't go too far, eh?

From: John
Topic: 3644 Message: 3676

HI All

I have this exact problem as well, I want to run my R-4A from a car battery.
I have been looking at the DC-4 in detail.
Being here in Australia they are rare as hens teeth. So I can not possibly test one.

Can anyone in this group provide first hand experience on using the 110V 300Hz output from the DC-4.

There is a few possible problems that I can see.
It is a square wave inverter, and as we all know, square wave have harmonics of every frequency in them, So just by using then within the inverter will cause RFI. This is why CPU controlled inverters make SO much RFI, it has little to do with the sinewave output.

300Hz is a fair bit higher than 60Hz, the iron in the transformer is made for 60Hz not 300 so it should get quite hot.

I have done a basic design of a NON-CPU sine wave inverter that uses a nice big transformer.
If uses an accurate analog sinewave oscillator that is than amplified, sent into the transformer and out comes the 240Vac Which is what we use here in VKland.
It works, but I need to design a feedback control so the output is better regulated.
At the moment the output voltage varies depending on the load.
The good news is, completely NO RFI except at 50Hz and it harmonics below 1000Hz

Is there anyone in this group that is skilled in analog power supply feedback design as I have no real idea what I am doing.

Regards John
VK2XCQ

Tim -

The information in the owner's manual is all you need to properly align the B-Line. My suggestion would be to ignore the 'alignment load' use, and just go through the adjustments several times on each transformer. I would also advise to NOT attempt the filter match item 8. regarding the wires twisted around transformer pins. This adjustment does not change, UNLESS someone has been fixing on it. This procedure can be a real bear, especially the first time or two you try to do it and is best left alone.

It is best to do the final adjustment of the INJ trimmers in both the Rx and Tx with the two units cabled together, using the correct INJ cable.

If you find repair is needed, you might take a look at my CD for the B-Line. It is a tremendous time and frustration saver if you work on these radios.

The Drake Technical net is on Sunday at 1600 EDT on 7.238 kHz.

John -

The DC-4 works just fine. The 'square waves' are smoothed quite well by
the iron and filter caps in the supply.

60 Hz transformer are MORE efficient and LESS lossy as the frequency
goes up. The receiver power transformer barely gets warm...

From: arsnf7z
Topic: 3644 Message: 3679

it certainly seems that the DC-4 would solve my problems. perfectly! obviously, the assumption is that it is rather noise free (after all, it was designed for this application), and that the R4C works well with the 110 VAC outlet (also designed for this application). I'm sure everyone know this, but the R4 series receivers do NOT like modified sine-wave inverters. I inadvertanly used one and the transformer was not happy before I could dive for the on/off switch! the DC-4 should work well.

now, where to find one? anyone have one for sale?

3680. substituting a 6FQ7 for a 6EV7

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-05-18 06:03:47 UTC
From: wa6neq
Topic: 3680 Message: 3680

Has anyone had trouble when replacing a 6EV7 with a 6FQ7? I have one 6EV7 and when I use it in either my TR-3 or TR-4C it works fine. However, when replaced with any one of the six 6CG7/6FQ7 tubes I have on hand, the transmitter becomes keyed as soon as the 6FQ7 warms up. VOX is set to min and anti-vox set to max.

Has anyone seen this problem before?

thanks,

Bill

Bill -

I've never used a 6FQ7, the 6EV7 is almost always cheaper!. But if you have them on hand..... Another story.

The 6EV7 was designed as a relay driver, while the 6FQ7 was designed as a Class A amplifier.

The only thing I can think of is that by the time Drake was using the 6FQ7, (because they could no longer get the 6EV7 in production quantities,) they had also dumped the 15k relay because of unreliability. Unless your TR-3 relay has been replaced, it's the 15k version, and the TR-4C could be either, depending upon serial number. When the 2.5k relay was used, a 1.5k resistor was installed in series with the relay, and this is the only version that used the 6FQ7 from the factory.

So. The easy answer is to get a 6EV7, which will probably last the rest of the life of the transceivers. If your TR-4C has the 2.5k relay, does it have the 1.5k resistor in series (usually installed across the tube socket)??

Otherwise, I'd check the voltages on the 6EV7 and 6FQ7 to see what's happening.

3682. Re: [DrakeRadio] substituting a 6FQ7 for a 6EV7

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-05-18 21:30:58 UTC
From: William Houghton
Topic: 3680 Message: 3682

Garey,

I haven't looked at either relay yet. I looked online and saw the 6FQ7 as a substitute for the 6EV7. I did look at the datasheets for the tubes a little while ago.

The voltage charts for the TR-3 show a 75V drop in plate voltage between receive and xmit for the plate that connects to the relay. If it is 15K, then the current through the relay is 5ma when operating. The voltage charts say that the grid voltage is -6V in receive and -0.5V when transmitting.

If you apply a 15K load line to the curves for the 6FQ7, with an open circuit plate voltage of 250V, a -6V on the grid will give you about 6ma of plate current, enough to close the relay.

I'll measure it later this evening.

Bill

Bill -

The 6EV7 curves show the -6V bias line at 0 mA at 250V, while the 6FQ7 with -6V bias doesn't reach 0 until less than 100V.

The TR-4C schematic that shows the 6FQ7 has R143 at 330k v. 680k, and R142 is 1M v. 68k.

The voltage chart says -9V for the receive voltage!

So it appears that the 6FQ7 is NOT a direct sub in the earlier TR-(any) transceivers.

Garey -

I think we are in agreement. In more than one place on the web, I saw the 6FQ7 as a sub for the 6EV7. Just goes to show that "subs" don't always work in all circuits.

I'll just have to find another 6EV7. I'll keep a few of my 6CG7/6FQ7 tubes in case I get a later Drake radio that uses them. At least we now know for the next ham who stumbles across this issue.

Subject: Re: [DrakeRadio] substituting a 6FQ7 for a 6EV7

Bill -

The 6EV7 curves show the -6V bias line at 0 mA at 250V, while the 6FQ7 with -6V bias doesn't reach 0 until less than 100V.

The TR-4C schematic that shows the 6FQ7 has R143 at 330k v. 680k, and R142 is 1M v. 68k.

The voltage chart says -9V for the receive voltage!

So it appears that the 6FQ7 is NOT a direct sub in the earlier TR-(any) transceivers.

>
> The voltage charts for the TR-3 show a 75V drop in plate voltage between receive and xmit for the plate that connects to the relay. If it is 15K, then the current through the relay is 5ma when operating. The voltage charts say that the grid voltage is -6V in receive and -0.5V when transmitting.
>
> If you apply a 15K load line to the curves for the 6FQ7, with an open circuit plate

voltage of 250V, a -6V on the grid will give you about 6ma of plate current, enough to close the relay.

Sometimes tubes are listed as straight-across substitutes and sometimes only possible substitutes, the difference is not always made clear. For instance, there are ruggedized verssions of some tubes, the General Electric 5-Star series for instance, that are electrically and mechanically identical to the prototypes. They can be interchanged freely as long as the special long-life characteristics of the 5-Star type is not required. In some cases "ruggedized" tubes may have different heater characteristics which need to be taken into account. One can sometimes get away with substituting a "similar" tube, for instance using a 12AT7 in place of a 12AX7. Some circuits will tollerate the difference but many won't work properly or even at all with the wrong tube.

3686. a question for Drakesters ...

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-05-19 13:49:24 UTC
From: arsnf7z

I'll admit to having way too much fun refurbishing Drake equipment from a bygone era. so far, I've brought back to life a R4C, TR4C, and recently received a T4XC that is almost perfect except for someone with a shakey hand doing a modification. they added a jack for a phone-patch, and tapped over to the microphone jack through a resistor.

my question is about the mic jack, the coax cable running down to the 12AX7 preamp and a 47K resistor in series between the jack and the coax. currently, the resistor is 'flying' .. one end at the jack the other soldered to the coax. I want to bring things back to normal, and just wondering if that is how the original factory configuration wired it. there really isn't much else they could have done, but it isn't clear with the modification that was added. it appears to be a 1/8 watt 47K resistor in series to the input.

anyone familiar with the T4XC enough to remember how the factor wired it? my concern is that the 47K resistor was originally down at the tube socket, and the previous owner changed this to give better access for his phone-patch mod.

now, I still need to find a RV4C and a MN-2000. the L4B will have to wait until someone in the Pacific Northwest sells. FedEx shipping charges are killing me .. but it has been great fun to get these wonderful rigs running once again and putting them on the air.

Daniel -

That is one of the few components that is NOT shown in my CD! :-)

Looking at the back of the MIC jack, the GND terminal is centered at the bottom (toward the chassis).

C109 is soldered to this terminal, with the other lead extending toward the front panel. R94 is soldered to the left-most terminal, and the other lead is connected to the "flying" lead of C109, forming a small triangle. The center conductor of the shielded wire is also connected to the common junction of these two components.

thanks Garey. it looks to be an easy change to bring it back to factory normal. I do wish that people took more care with their soldering irons when they work on the jewels. way too much heat, with melted insulation and scarred coax jackets. not to mention solder splashes and flux residue. I suppose this might be an artifact of the age, when everyone used those massive Weller guns with 1/4" tips and high-wattage!

luckily, this was the only mod on the T4XC, though there must have been a problem with the oscillator board at some point in time, as they melted the wires resoldering them to the board. no problem cutting them back and soldering them correctly. I was also pleasantly surprised to find all the aux crystals loaded up for 160 and 10 meters.

the only other issue I am having is the observations from listeners that there are no lows from the Shure 444. this makes for a great DX signal, but I think these days the expectation is for a more rounded bottom-end, that the Shure can't provide. so, my next task is to find a microphone/preamp to yield a better response on AM, that doesn't go through the bandwidth limited SSB filters. anyone stumbled upon a combination that works well on AM?

OK. I was on my way out to rehab this morning, so written in a bit of a rush! :-)

That network is at least in part an RF filter, so both components need to be right at the input. The cap is smaller than a bypass to avoid rolling off the top end of the audio too much. Drake claimed that the best microphone to use was one with a flat frequency response, as the "shaping" of the audio was done in the transmitter. The 444 has a rising peak starting at about 1200 Hz, rising sharply (+12 dB) at 3 kHz, then dropping back to zero dB at about 5 kHz. The low end is down 3 dB at about 250 Hz.

I like the E-V 644, which is relatively flat (+/- 3 dB from 200 to about 12 kHz) with the peak area between about 3 - 7 kHz. Unfortunately, Collins chose to use this microphone with the S-Line in some of their ads, so the price has been driven up considerably above similar mics.

Since you're working in that area anyway, you might want to try a 470 pF for C109 to tame down that peak. Of course voice characteristics can exacerbate peaks and valleys in microphone response curves too.

Art, N4JK, has an interesting page on the D-104 at

<http://members.cox.net/n4jk/d104.htm>

If you want to tailor a D-104, the article by Alan, W2AEW's circuit is here.

<http://www.qsl.net/w2aew/myd104amp.html>

The D-104, "barefoot" does a pretty good job on the Drake transmitters, with a series resistor in the plug to adjust the low end as necessary to accomodate your voice characteristic / preference.

3690. Drake DC-4 DC power supply and cable, or alternatives ...

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-05-25 16:31:11 UTC
From: arsnf7z
Topic: 3690 Message: 3690

in addressing my problem with powering Drake equipment on a sailboat, we explored a few possibilities; the best one seems to be locating a DC-4 DC power supply. they appear to be extremely rare .. so, please, anyone having one for sale, or knowing someone with one for sale, I would appreciate a response. I did find a DC-4, here, but it was offered 'as is' with no connecting cable. $70 for something that may very well be a paper weight (with no cable), isn't a good investment or risk. the fact that the cable is missing portends poorly in my view.

other than that, I am still open to recommendations for a noise-free DC/AC Pure-Sine inverter, as possibly used on Field Day. this must be a common problem for Field Day devotees, though I suspect that a gas-powered generator with ignition-shielding might be all that is required in many applications.

Daniel
Guess you don't know me very well!
I have never sold anything that didn't work as described and I never would.
If I sent something un-tested and it came up with a bad report I would buy
it back including the shipping--no hassle---no questions. Plain and simple
it is my way of life---my way of doing business
I was going to sell it with the cable tested and gauranteed $100.
I don't have or can't find the cable and the time and expense of rigging it
up prompted me to offer it for less. Let someone else invest in testing it.
If it doesn't work they get their money back.
The DC4, TR4C, T4XC, R4C, L4B and several AC4 supplies all came from a
professional getleman who had them all since they were new. Everything else
worked exactly as he said. He wanted the simplicity of sending it all to a
new good home and that is the way I bought it. In fact, he sent the gear and
I received it before I even had gotten around to mailing his check.
Sounds like a better place to be in life. As for why isn't the missing cable
there--who knows, the extra microphones and tubes he generously gave me
certainly makes up for a missing cable or two (some of the R4/TR set were
missing too). Maybe I should call him on that
If you want the DC4 I will clip lead 12 v to it and see if it puts out the
right voltages but you will have to come up with your own cable.
Paul

is there an issue with Yahoo groups email? I've been conversing via private email, and Paul's email to me is public. there is no need to discuss this matter publically, and I was careful not to mention any names in my previous posting.

Paul,

I certainly wasn't questioning your integrity. if you would give me my money back, that would be grand if it didn't work. I interpret 'AS IS' to be exactly that. you buy it .. it's yours. I think it is a logical extension to ask the history of the power supply. to get a complete Drake rig, including the power supply, extra microphones ... and yet, not receive the matching cable to the DC-4, would lead anyone to the conclusion that something happened along the way. the only scenarios I can think of, is that the owner forgot to give you the cable, or that the power supply was never used and no cable existed, or the power supply died and the cable was tossed. seems unlikely .. but the cable must be somewhere! <grin>

the cabling and connector are not a restriction. a dead DC-4 without the parts to fix it, would be. the best resolution, is to have you test it. if it is indeed, dead, then you would not want to sell it 'AS IS'. unless someone wants one for parts, of course. as the seller, I would think you would want to do that, or, sell it 'AS IS' and let the buyer take the risk. that seems wholly unfair to me (and a waste of time), when a few minutes with a power supply and a couple of clip-leads could address any doubts on both ends.

no slight intended ... just a buyer trying to determine what you are selling.

3693. FS: Drake 4-line 30m Crystals

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-05-26 00:40:29 UTC
From: Bry Carling
Topic: 3693 Message: 3693

FOR SALE: Drake 4-Line 30m Crystals

This is the PROPER recommended crystal as described for
Drake equipment to be used on the 10 MHz band.
Great for your Drake T4X and R4B etc.

If you use 21.100 MHz crystals which would be the "normal" ones
to use, there is a severe reduction in sensitivity.
For best band coverage you need a crystal on 20.800 MHz.

I have had just a limited number of these made up for Drake owners.

They are currently available for $35.00 each and when they are gone,
that's it for the run.

Get the best performance from your Drake 4-Line equipment
on 30 meters.

Contact me off the list if you would like some of these.

SUBJECT: [drakelist] 20.8 MHz (30 Meter) T-4XC Crystal wanted

-----Original Message-----
From: Garey Barrell
Sent: Sunday, February 27, 2005
To: Eric Webner; Drakelist
Subject: Re: [drakelist] 20.8 MHz (30 Meter) T-4XC Crystal wanted

Garey Barrell made an utterence to the drakelist gang:

Eric -

There is a very good reason for using the 20.8 MHz crystal instead of
the 21.1. There are several spurious outputs in and around 10 MHz
when using the 21.1. This is specified in the T-4X(any) manual with
"do not use" ranges for certain crystals. Keep in mind that the PTO
operates in and around 5 MHz.....

And yes, you can transceive on any crystal you have in the receiver,
but the same problems occur with a 21.1 MHz crystal in the R-4(any).
If you just want to listen to 10.1 - 10.150 the 21.1 MHz crystal will work
in the receiver. But don't transceive using that crystal. Transceive isn't
all that satisfactory on CW anyway, since the offset is around 900 Hz
and most folks like to listen to CW at a somewhat lower frequency.

73, Garey - K4OAH
Atlanta

Eric Webner wrote:

>I wonder if the 21.1 Mhz crystal would work as well. It sure would be
a lot easier to operated the vfo, since the band would start at 10.0
Mhz instead of 9.7 or whatever the manual says.

Can you experts tell me what it takes to transceive on accessory
crystals? Can I get a crystal for the receiver, set the T-4XC mode
switch to "RECEIVE" and be able to transmit and receive on the 30
meter band?

73,

Eric KA8FAN

David Havel wrote:

Hello gang,

I'm in search of a 20.8 MHz crystal for my T-4XC in order to put it on 30 meters. According to the manual, the 20.8 unit is the only recommended crystal for use on this band. If you have one you'd like to sell, please email me what you're asking for it!

Thank you in advance & 73,

David Havel - NO3K

3695. T4XB AM distortion and a receiver problem

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-05-26 23:16:21 UTC
From: Richard Knoppow
Topic: 3695 Message: 3695

I discovered my T4XB has a lot of distortion on AM.
Its especially noticable as "spitty" highs and there is some
splattering and it sounds "clippy". Its not overmodulation.
The voltages at the 6AU6A modulator are close to those
specified. Is this a common problem, if it is perhaps
someone could save me some tail chasing.
Also, a couple of days ago a mysterious problem showed
up in my R4B. When the mute is on for any length of time
(several seconds or more) the neon indicator lamp won't come
on again. The mute circuit itself seems to work OK. When the
problem happens I get a higher than normal voltage across
the leads to the lamp on the circuit board. That sounds like
the lamp is going open. Has anyone experienced this before?
I will try to find a replacement lamp but I am wondering how
it could be intermittant in this particular way. Turning the
receiver off for a minute or two will light the lamp but
does not actually fix the problem.

Well, I have a good audio generator (General Radio).
The mystery is that SSB is fine, just AM has a problem.
Also, the side tone seems OK. I tried replacing the 6AU6 and
12BY7 tubes with no change. Next will be C-134 but I would
think if it was leaky it would show up as a shift of the
bias at the 6AU6 grid. Anyway, I think I will hook up the
audio oscillator and scope and see what it shows. I just
thought someone had experienced this before and would know
the exact cause.

I'd say the 1st thing to check is the bias setting on the controlled carrier modulator. The Drakes I know are different from other SSB/SM transmitters as they actually have two modulators.

I am unaware of any way of setting the bias for the modulator. I agree that if its off it could cause the problem. I am about to run some tests with an oscillator and scope and may replace the coupling caps just on principle but I don't like shotgunning stuff. Unfortunately, the only voltages given are for "Tune" and may be quite different in other modes. I may never use AM but I don't like to leave things half-fixed.
Also, I don't quite understand what you mean by two modulators unless one of them is the balanced modulator for SSB. It appears that the controlled carrier modulator is the 6AU6 modulating the screen of the 12BY7 driver stage. The 6AU6 seems to do double-duty as the side-tone amp in CW. This seems to work OK but has some distortion when both the side-tone/anti-vox control and the main gain control are wide open, not a position I would normally use it. Anyway, I will report back on my measurements.

Hi Richard -

There is no adjustment for the bias on V11. You can put a resistor in the lead from the Plate up to the Screen of V4, either a pot or selected resistor to get the idle current you want. Parallel the resistor with a 0.47 uF capacitor. No more than 15-20W output from the PA with no modulation.

Have you checked R58? Those high value carbon comps are particularly prone to going up in value over time. I'd check R56 and R57 while you're in there just to be sure.

The problem with the PTO indicator lamp in the R-4B is that the firing voltage of the NE-2Es goes up with age, and the resistive divider across Q10 is fairly tight. Drake's fix was to just cut out R150 to allow that firing voltage to increase. Changing out the bulb isn't too bad if you have three hands! You have to pull the front panel, cut and resolder the leads to the new bulb and then reassemble the panel, the bulb, and the shield without breaking a lead off the bulb. The replacement bulb has to be short enough to fit in the shield, which unfortunately is shorter than the maximum allowable length of the bulb. Most are short enough to fit, but check before you're almost through with the re-installation!

What is typical output, mine has only about 5 watts when keyed but without modulation.
I think I checked all three resistors but will check them again.
I will try lifing the 150K resistor on the receiver. The voltage when the lamp does not fire goes up to around 101 volts but only to about 91 when it does fire. Of course the lamp is not drawing current when not fired. I don't know what the firing voltage is supposed to be but lifting the resistor seems like a good cure. I've had the lamp out, its a bother but doable. I know what you mean about lead length. Its one of those jobs where there are no short cuts.

R-150 was the problem. I started out by just lifting it
decided to measure it, about 88K. This was just enough low
to cause a problem. While carbon comp resistors normally go
high evidently they can also go low. In any case replacing
it with a 100K film resistor seems to have fixed the
problem. Its also possible that the old resistor was
temperature sensitive, I've not checked it for that but
after running RX and TX for more than half an hour the PTO
light still works. So thanks for pointing me in the right
direction.
I have yet to complete trouble shooting the AM problem.
On AM I get lots of splatter especially if I blow into the
microphone. Intermod distortion perhaps? Anyway knowing the
normal amount of carrier in the absense of modulation would
be a clue.

Checked all three and all are very close to the marked values.

Richard -

OK. Yes, sometimes carbon comp resistors do go low in resistance. R150 is there to limit the voltage on the transistor, so it's better that it's in there. Interestingly, the 2N3877 is only rated for 75 VDC Vceo. The divider results in about 110V at the junction of R150 / R151. Of course there is no voltage on the Collector until the NE2 fires, and it drops ~ 65V once fired. Minimum firing voltage is 90V. By the way, the NE-2E is now known as the A9A. Some have replaced the NE-2E with the high brightness version (NE-2H for example), only to find that after they got it all back together it still didn't work! The "H" versions drop ~95V and takes 135V to fire!

Typical output on AM with no modulation is ~ 3-5W, so you're in the ballpark. This is "controlled carrier", as opposed to "screen modulation", chosen to limit the dissipation in the PA. Theoretically the carrier power comes up with modulation to maintain the balance needed. Some don't like it because the receiver S-Meter swings around like it's on DSB. I have heard some that sound great as designed. There are several simple mods to convert to screen modulation, I'm not sure what effect they might have on SIDETONE operation. I've never played with AM, preferring to use "real" AM gear such as the Viking Ranger, Viking II, DX-100, 32V-3, etc.

After fooling around a bit I am not sure there really
is an AM problem, it may be an artifact of the way I am
testing. SSB sounds fine. On the scope the AM looks about
like it should, that is, a varying amount of amplitude of
the overall envelope but with about constant modulation
percentage. I don't hear any distortion (at least not gross)
on a single tone. I don't have a second oscillator available
to make two-tone tests.
I check the audio quality with the AVC off and fixed,
rather low RF gain. The test receiver is a Hammarlund
SP-600-JX on the other side of the room. There is enough
radiation from the dummy load, or perhaps directly from the
TX, to get a usable signal on it. At any rate, I am going to
do a final check on tuning and button the thing back up.
Thanks to all those who helped.

This is pretty much what I do. I use a direct connection with an attenuator from the headphone jack of a small radio to the mic input. The attenuator also serves to present both sides with the correct impedances. It seems to me that I got cleaner sounding AM at some point in the past than now but can't be sure. In any case, I don't intend to use the TX for AM but I like to have everything working right. I just rechecked tuning since I have the covers loose, all seems to be on the nose. I think I will button the thing up. The RX is still working right. I need to get busy and rig an antenna.

After fooling around a bit I am not sure there really
is an AM problem, it may be an artifact of the way I am
testing. SSB sounds fine. On the scope the AM looks about
like it should, that is, a varying amount of amplitude of
the overall envelope but with about constant modulation
percentage. I don't hear any distortion (at least not gross)
on a single tone. I don't have a second oscillator available
to make two-tone tests.
I check the audio quality with the AVC off and fixed,
rather low RF gain. The test receiver is a Hammarlund
SP-600-JX on the other side of the room. There is enough
radiation from the dummy load, or perhaps directly from the
TX, to get a usable signal on it. At any rate, I am going to
do a final check on tuning and button the thing back up.
Thanks to all those who helped.

Test the audio by recording it and listening to it later. That's better than
listening to it real time.

>They almost always go up in resistance with age...

The operative term is "almost."
I once chased my tail on a Navy loran set (APN-70) whose timebase was
running high in frequency; the plug-in crystal was OK.
Decoupling resistor to the oscillator tube had gone virtually shorted, and
the high B+ apparently overdrove things and caused the problem.
We were much more accustomed to open resistors, usually with the obvious
loss of internal smoke.

Hi Jim..

Not doubting you...

But.....

You say it is a speaker connection for the 3 and 4......My question is...how? There is no wiring between the speaker and the AC-3/4....The PS just sits in the speaker housing. There is a long pigtail that comes directly off the speaker and goes over to the R4-B. The pigtail I ask about is only 6 or so inches long and is wired directly into the power plug. It never 'sees' the speaker or speaker housing. I guess I need to look in the plug and see what its pin-out is...might answer my question.......it sure isn't shown in any of the manuals I have or the schematics either!

Does the TR-3/4 have a powered speaker? It could have been a power tap for that....or for an external VFO???

It is not for use with the T-4any or R-4any. It is the speaker OUTPUT for the
TR series transcievers only. It has no function on the seperates.

So....instead of plugging the long speaker cord into the TR-3/4, it just plugs into the short pigtail and the speaker connection is made through the master power plug when it is plugged into the TR-3/4. Interesting.

Thanks!

Joe -

As others have said, that pigtail is a speaker output when the AC-4 is used with the TR-3/4 transceivers. I believe the original thought was to have just one connector and one antenna lead to pull the radio out of the vehicle.

One caveat.... The AC-3 power supply was designed for use with the TR-3, before the T-4X was designed, but the AC-3 was sold for the early T-4X transmitters. It had NO connection for keying an external amplifier, not even the nutsy two pin connector that was on the AC-4. So... There are more than a few AC-3 power supplies floating around out there that have had that little pigtail "repurposed" as an external amp keying connection.

If anyone has pinout for the AC4 perhaps it could be posted in FILES section. Most interested in the pin assignment for the audio from the TX.

Thanks.
Reading the schematic the signal to RCA is on pins 7 and 12. Looks like 7 goes to ground. I'm wondering on what pin the center from TR comes from. THX

Drake crystals - 20.6 = covers 9.5 - 10.0 Mhz Short wave band..
26.6 = covers 15.0 - 15.5 Mhz Short wave band
38.1 = covers 27.0 - 27.5 Mhz CB band
39.1 = covers 28.0 - 28.5 Mhz Ham band
37.6 = covers 26.5 - 27.0 Mhz CB band

All crystals $15 plus $5 shipping.. bundle with several and no extra shipping costs. I take Paypal and MO.

I've been having way too much fun of late, buying and refurbishing Drake equipment. are there any dedicated "Drake users" nets where other afficionados of fine electronic equipment get together and chit-chat? just casual on-the-air banter about equipment of that era. Drake, Collins, Hallicrafters, National? it's been great to see many of these old rigs, rigs from my own beginnings, now falling into favour once again.

Good information.

And to think I had looked at that pigtail pondering that someday I had to figure out how I could interface my Drake B-Twins and a Heathkit SB-220 linear amplifier with that! (Just thinking...I had not done anything about it yet.)

Thank you.

Grant:

I can't comment on the lettering, as I have never tackled that.

However, I did have some of the usual corrosion and even had some green oxidation. I had to clean it down to the steel chassis and then I re-plated it with copper. I can't remember what company I bought the solution and plating pen from (I think they were in Florida), but a few years ago it was about a $40 investment. It's not perfect, but it is a heck of a lot better than it was.

JB -

Judging by the specks, it looks like the one on my CD's. :-)

Yeah, loss of Ron's site would be a real loss to the Drake community.
There are partial collections elsewhere, but none so complete. I wish
he had used a higher resolution to scan them, but, he got them done! I
reworked the scans that I made of the big schematics, in most cases they
are better than the originals. Several guys have said they printed them
out at a Kinko's, etc. in a 2' x 4' size.

Drake still has a fair collection, but I suspect it is disappearing
fast. Can't have them in too many places, as sources disappear overnight!

FOR SALE: Chassis And Cabinets for radio and electronics
construction etc.

New and used metal boxes, chassises, mostly in the
range of $2.00 to $6.00 each.

Some cool traditional cabinets and sloping cabinets for homebrewing.

New and used cabinets are suitable for building radio receivers,
transmitters, test gear etc. and range from $2.00 to $15.00

See web site for photos, dimensions and full descriptions of
these... while they last. Save money - combine for reduced shipping cost.

3749. PTO tension adjustment

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-04 19:48:23 UTC
From: arsnf7z
Topic: 3749 Message: 3749

in a perfect world, all the PTO's on my four Drakes would have about the same tension on the main tuning knob. they are close, but if there is an adjustment I could bring them all together. I recall mention that there is a way, though it wasn't necessarily recommended.

73's

From: Garey Barrell
Topic: 3749 Message: 3750

Daniel -

There is a small allen set screw on the back end of the PTO lead screw. Later PTOs have a hole in the cover to allow adjustment, but I'd recommend removing the cover the first time you do it. It's not that it's NOT "recommended", just that you need to be careful to not disturb the component placement inside, hence removing the cover! Of course the earlier PTOs didn't have the hole, so ... :-)

The covers are relatively easy to remove, just takes patience. The spring clips on either side need to be "compressed" (the tines pushed toward the space between them). I find it best to use needle-nose pliers to move the clips one leg at a time just enough to clear the barb on the leg. Then holding pressure, (or inserting a small shim to retain the ground gained!,) compress the other leg of the same clip. Then tilt the cover "slightly" to loosen the grip of that clip and go to the other one. It's really a lot easier than it sounds, especially after you do it a time or two.

Depending upon the model, you may want to remove the tube directly behind the PTO to allow clearance to slide the cover straight back and off, again being careful to not disturb any components inside.

Don't overtighten the set screw, as this overloads the front ball bearings. Best to just take the "play" out of the MAIN tuning knob shaft so there is no lateral movement.

From: Kris Merschrod
Topic: 3749 Message: 3751

Daniel,

The size is a 3/32" allen wrench. It is tricky, remove the cover as Garey says, plus remove the first tube. It takes a bit of patience so put it on a bench with a chair so that you can easily lean over it. Crank down gently and with each slight move, test for feel.

3753. FS -- Early two tube, silver border RV-4 AGN

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-04 23:54:28 UTC
From: Kris Merschrod
Topic: 3753 Message: 3753

Hello All - Back again - interested party fell through

This is a nice Drake accessory - provides a speaker, and a place for the AC-3 or AC-4 plus allows split operating for the TR-3 or TR-4 lines.

I have for sale this early RV-4, Two Tube version (OA2 and 12AU7) Later models were single tube. Face plate is very clean (has the silver trim around the perimeter), the cabinet is dull and scuffed in places. The chassis (copper plated) has the usual "freckles" and underneath in one corner it is "rusted." I have tried to use it with my late model TR-4CWx and it only works in one position and I can't figure out why.

Although I have the original speaker (it was buzzing) and will include it, I have installed a new 4 ohm speaker.

Who will give me $125 for it?

Jb -

Not a problem. I "borrowed" it as well I guess. That part of the CDs
is just to put stuff on the CD that is available on the internet. The
annotated photos and parts lists I get a little testy about! :-)

3755. Drake L4 Amplifier

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-05 01:40:03 UTC
From: COREY
Topic: 3755 Message: 3755

Greeting to the group, I'm still having an issue with a older L4 amp, Getting 100MA of plate current in idle mode, Already tried changing vox polarity. I did have someone install a softstart for me, Anyone have any ideas? Thank you in advance, Sure am glad this group is here..73, God Bless..

Corey a pair of 3-500Z's running on a Drake PS should probably be drawing about 100ma or more of idle current. If anything it is a bit low for SSB position.

Thanks Paul, The L4 is running twin 3-400's...So it's ok to see the 100Ma, even in the un-keyed position? Guess I didn't mention that part, I'm not use to seeing that. Have been thinking about putting the Mod in from Gary Drommond K40R electronic bias switching..Thanks again, 73

Sounds like the relay is still pulled in. Unplug the VOX relay line in the back of the L-4 and the plate current should be zero. Flip the plug over and reconnect. The 4 series have an isolated set of contacts and the wires came out through the AC-4 supply to the L-4. Since there was no grounded side the L-4 worked fine. TR-7 and other rigs have one side grounded on their VOX relay line so now it is critical to make sure that the VOX relay plug is matched to the L-4 ground.

If the plate current still reads with the relay line unplugged then there is a much more serious problem that needs to be fixed.

Larry, Have already tried changing the polarity of the vox plug, It didn't help...Other than this problem the amp works great...Have already rebuilt the power supply. Not sure If there is something that I did that caused this. Also put a softstart in, Maybe I should take the softstart out and see if that changes anything, Thanks for your help...73

I doubt that the soft-start is the problem. It would be in the primary side of the PS, and your problem is in the tube circuit. You say otherwise it works fine, so something is causing a grid current indication in RX. The tubes are not getting cutoff bias for some reason. Dirty relay contact, miswire, short, bad component ... ?? You need to understand how the circuit is designed to work normally, then do some troubleshooting - taking all appropriate precautions when working with high voltage. This stuff can kill you. Seriously.

Larry, Still get the 100ma of Plate current. Everything else seems to work fine. I even made a very short contact driving it softly with Drake B-line. Got a great report. Could it be in the 50k Bias resistors in the supply? Appreciate you, & Everyones help, I'm still in the learning process...I have both a sb200 & sb220 that I never had this kind of problem with. Thanks

From: jkimento
Topic: 3766 Message: 3766

I bought a drake sw-4 receiver at a ham fest today
serial #10
add this to my drake small collection
my question is has anyone found a replacement for the blue filters
I dont really want to use blue led's or paint the lamps

Is there a source for the blue filters

thanks
jerry

The answer is yes. There are about as many ideas as there are Drakes. See here:

3769. Bob N3JQD TR4 problems.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-06 22:58:29 UTC
From: bobsalmon@juno.com
Topic: 3769 Message: 3769

I'm new to your group,but, not to Drake equipment. I have two "4-lines"
in operation and just bought a TR4.

The TR4 works as expected on 80m. I just spoke with Kris, KM2KM, for an hour. He said that the audio was good and signal was steady.

My TR4 is s/n 28005 with a functioning AC4 PS. My trouble begins when I switch from 80 to any other band. For example, on 40m I only hear some sound when I switch it to USB mode. LSB is almost silent, Just very light white noise sound. No actual QSO's can be heard. This is also true for the other bands.

The next problem is when tuning the output. On 80m for instance where the rig works. I set the proper Band and Sideband controls per the operators manual. There isn't any output. But, as I switch off from X-CW, to SSB , it mometarily keys the xmit. Just briefly. So, to get any output I've been humming the word "5" over and over.

Any ideas would be very much appreciated.
Thanks ahead of time.

Hi Jerry!

Funny you should ask this question!

I **just** obtained the gel sheet and am in the process of replacing the filters in all my radios.

The gel you need, is Lee Lighting, #172, Lagoon Blue. You should be able to find it at any theatrical lighting supply house. The cost will be in the vicinity of $7.50 plus shipping and/or tax. It will be a 24" x 22" sheet.

If you have a problem finding it, You can contact Bright Productions, 1289 Spice Islands, Sparks, Nevada, 89431. 775 331-1800. That gel is a stock item.

Good luck and have fun!

There is undoubtedly a lighting gel that will match
pretty closely. The main supplier of gels currently is
Rosco, see: http://www.rosco.com/
for more. A Google search for "lighting gels" will find
retailers. Rosco has a sample booklet that will help match
the color. You might try Calumet Photo
http://www.calumetphoto.com they sell Rosco filters retail
and could help decide what you need. The stuff is not
expensive, less than $10 US will get you a lifetime supply.

I just posted a reply suggesting Rosco filters, Lee is
the other maker and either should have the right color plus
lighting filters tend to be fade resistant.

Bob,

Great old rig, lots of them are still on the air especially in the
winter months when the extra heat of the tubes is appreciated in the shack.

First problem: On 80 tune in the calibrate signal. Switch to the other
sideband and retune in the calibrate signal. The S meter levels should
be equal. This checks the filters to be sure both are working. Switch
to 20 meters, and tune in the calibrate signal. This test shows the
receiver is working in its "single conversion" mode. This is why 20
tunes in reverse.

Switch to 40 and tune in the calibrator. If there is no signal then
something is wrong or the crystal for 40 is missing. This is the
"double conversion" mode which is also used for 15 and 10 meters with
appropriate crystals.

Second problem: Unlike the "Twins" there is no separate Tune position
so the sideband switch must be placed in the X position to the right as
you are tuning the rig in the CW mode. If a key is plugged in it must
be closed too.

Let me know how it goes.

Ivan,
The L4 had 3-400Z tubes while the L4B had 3-500Z tubes. The L4B also has the front panel AGC control knob/switch.

The supplied tubes are differant. L4 used the 3-400 and the B uses the 3-500. The B has an AGC control that also has an in/out switch for the amp. The AGC control/switch is moved from the back of the L4 to the frount or the B. Breaks the circuit to the antenna relay.

One big differance is the B version has added positions to the meter switch that includes a built in wattmeter that reads 3000 watts forward, 300 forward and 300 reflected. The L4 just has a relative power position with the adjusting pot on the back of the amp.

3780. Drake Blue Filter History

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-07 17:12:48 UTC
From: John
Topic: 3780 Message: 3780

Greetings.

On another site I found the following comment:

"Best of my knowledge Drake always used blue filter material. As most of use has witnessed over the years with age the blue filter material would fade in the area of the #47 lamp and the white plastic dial background would yellow. The result was a green colored dial background. The S meter would appear as no filter was installed at all because of the fading, just colorless lamp light."

When I first acquired my used Drake B-twins, they both had plain white dials. I've been trying to remember other Drake radios I have seen over the years and the first time I can remember seeing a blue dial was on the TR-7 series. Down in Quito they were throwing a SPR-4 out - which now I wish I had rescued. But I seem to remember that it also had a white dial, albeit slightly discolored.

Can anyone help by clarifying this bit of history?

Thank you.

John

Topic: 3781 Message: 3783

To Ivan KB1STH,

As far as I've read, the RV-4 had a 2 and 3 tube variant, but it works identically to the RV-4c which is solid state. The RV-3 is a 4-tube design, but will also work, with mild modification <grin>.

I have a Covelli refurbished TR-4 with a RV-3. The whole thing works great! I was lucky in that my RV-3 had already been properly modified, and the tubes still work. I use the RV-3 because I prefer the audio from its' very old speaker to the audio from my MS-4 speaker.

The DC-3 should work (slightly different design, but work alike). However, it only has enough power to operate one transmitter/transceiver at a time. Don't attempt to parallel them. And because it was designed for the tr-3 transceiver era, it probably does not have the speaker wire in the power-supply harness to the radio, as the AC-4/DC-4 does.

I'm just starting out with Drake too, so I might be erroneous at points. Hope the info is of use, have fun and good luck!

Welp...

Today, I picked up a 4 pack of Number 44 bulbs for my B Line.

Gotta say, BOY!! DOES THAT MAKE A DIFFERENCE!!!

Nice and bright...good color blue.....Well worth the $3,86 spent.

Now to replace the blue film in the 2 meters. Not real excited about pulling the whole faceplate to remove the meter, but it is just time consuming, doesn't look difficult. It will be worth it in the end....I'll take pics when I job is complete and post them..so you LED weenies can compare! <<GRIN>>

The No.44 is higher wattage than the No.47 and is
brighter. I think it may also be somewhat longer lived.
There is another lamp, someone will remember the number,
which is higher voltage and has perhaps ten times the life
if either of the above with some reduction of brightness.
When disassembling the front panel be careful not to
lose the spacers under the screws. While you could make new
ones its better if the originals are not lost. They have a
way of falling out. Take the panel off with the front of the
radio facing up.
BTW, I often work in a shallow box to catch any small
parts that drop off. I do this with cameras and other small
stuff. Another trick when working on small assemblies is to

work in a plastic bag which will catch any springs that go flying. You can work in a perfectly clean, empty, room and still have parts disappear:-(

There's a spacetime warp zone 1/2 inch above the floor of any room where such detail work is being done. That's where those screws go that you SEE fall to the floor, and you HEAR the spot they hit the floor at, but they can't be found anywhere within 500 yards of that spot.

I think I have faries or gemlins who get curious about
stuff and make it disappear and then return it later. I
dropped a pencil the other day, I _felt_ it hit my foot. Not
there, got on all fours and searched, nothing. Next day
there it was right under the table where I was sitting. I
swear I searched that exact spot several times. I've also
found small parts, screws and washers, weeks or even months
later.

BTW, odd socks, especially the longer sweat sock type,
work like a charm for using up bits of soap. Stuff them into
the sock, you get it wet and use it was a sort of washcloth.
The sock filters any stuff on the soap and stays clean
itself. Also, its easy to find it you drop it. I keep one of
these in my shower.

I've heard they like shiney things. A local mystic advised me to leave a bribe of some pocket change and ask them to return the missing parts. So far, they like the parts better than the change...

Good tip, I'll remember that. My old socks tend to end up as oil rags in the trunk or under the hood of my car.

From: arsnf7z
Topic: 3792 Message: 3792

or, the frustration of finding a MS-4 speaker replacement.

seems simple enough. the old 5x7 speaker was a replacement of a replacement, and after all these years the rubber had decayed into dust. this particular speaker replacement was a Jensen with a 10oz magnet and sounded really good. had a nice round bottom-end that jazzed up AM signals. reminded me of the old and huge speakers of the National, Hallicrafters, and Hammarlund days. remember those boxes?

I got on Amazon and found a BOSS 5x7 speaker for $10 that looked like a reasonable first attempt for replacement. unfortunately, newer speakers are more oval (actually, more circular) and the height dimension is generally greater (by about .25") than the MS-4 cabinet affords. for testing, I snipped off a bit of the frame and installed it, just to see how it sounded. I can't say I am impressed. it's mostly lows, and muddy. so, I started looking at alternative speakers from Alpine, JBL, Infinity .. but they all seemed to be just a tad too big to fit, or the tweeter sticks out beyond the face.

I have had a philosophical objection to buying anything from Radio Shack, though I heard there used to be a replacement available. I couldn't find it in the catalog listing, and to be honest, I would like to use a better grade speaker.

has anyone had luck finding a good replacement speaker, that sounds good and fits without modifications? I have found a few high-end variants that look to fit (if barely), but they're ~$60 per speaker and overkill.

Daniel
I share your frustration
The speakers with the extended frequency response manufactured today for automotive market just do not do it for me. I don't care how "good" they are, they were designed for a different venue driven by a totally different source and, IMHO, will not sound as good on the ham rig as that old 6 or 5X7 or 6X9 with the alnico magnet.
One thing I have studied a bit is to examine the response curve of the vintage speakers and compare it to what I measure with other speakers available today. A pair of 3" cheapies salvaged from a low end tv set is not a bad place to start.
A friend utilized an alternative with a 15 band graphic equalizer to drive a "hi fidelity" amp and speaker with the vintage response derived from the equalizer.
I came by these observations rather early in ham radio when I got my first R4. I did not have a MS-4 and I assumed that a metal box of the same size fitted with a pair of 5" high quality, extended response drivers would sound terriffic. It did not and I soon acquired an MS-4
Jensen does manufacture a couple of vintage speakers but unfortunately they are only available in 10" and larger

Try
http://www.surplussales.com/microphones-audio/MicroAudio-8.html

Drake probably use an RTMA standard speaker. Impedance
is not critical.

>
To add to my last message, for the most part the
speakers supplied for boatanchor radios were pretty simple,
just open back boxes. The response of a speaker in one of
these is limited in the bass region and has a resonance due
to the box. Closing the box extends the bass but increases
the resonance. Filling the box with absorbent material such
as fiberglass will often improve the responce because it
damps out some of the resonance. If you want to get better
sound I suggest mounting the speaker in a fully enclosed
wooden box of sufficient size filled with absorbent. For a
small speaker of the sort used in the Drake box a volume of
about one cubic foot is sufficient. Usually these speakers
have a fairly high free-air resonance so the volume of the
box can be fairly small without unduly raising it. The
pentode output stage in most tube radios has a high
effective impedance, i.e., not much damping, so the
fundamental resonance of the speaker and box will be
exagerated. This is not much of a problem in most of these
receivers because the low end is limited anyway.
Note that _small_ hi fi speakers are made to trade
efficiency for good low end responce. The amplifiers in
receivers like the Drake R4 and similar is quite limited in
power output, probably not more than one watt for reasonable
distortion, so you want a speaker with decent efficiency. A
small speaker designed for speech frequencies will usually
do. If you want lots of bass you need either a very large
speaker system or an external amplifier.
Oval cone speakers were developed mostly to fit into
limited cabinet space. While some claim they have better
frequency responce or distribution I doubt if there is
really much difference.

A full re-cone may not be necessary. Orange county speaker sells the surround foam kits ("re-edge kits") to fit a wide variety of speakers, they may have something that would work for the Jensen. I bought a complete kit for my Bose 901s years ago, and couldn't have been happier with the result or the customer service. The repair was really a lot easier than I thought it would be, no issues, and the result sounds great! A communications speaker should be easly comparatively.

http://www.speakerrepair.com/

Oh, and they also do re-coning....

Welp...my warp zone today was from desktop to the floor. Took the front off the R-4B to replace the color gel in the meter. **EVERY** screw went into my magnetic screw and parts catcher. I made sure the screw hit the magnet!

Yet.....

When I reassembled the radio, one case screw was missing. Where was it? On the floor, between my size 13 tennies! Have no clue how it migrated down there, let alone how it stayed there with all my standing up and sitting down while reassembling the receiver.

Hey...and Richard, you neglected to tell me to watch out for spring washers under the dial indicator adjust 'knob'. Shame on you....Oh well, you DID warn me about the faceplate spacers so all is forgiven. <<GRIN>>

Oh well...The radio sure looks nice.....I will probably do the transmitter tomorrow..then I will take a low light pic and share it with everyone.

And..for what it is worth...my 'new' L-4B will be here Sunday....it was pricey, a grand, but...it has new (NOS) Eimac 3-500Z's in it and the power supply has all new diodes...I will probably replace the resistors and install a softstart circuit in the system.

No shipping..my business partner is picking it up Saturday on his way back to Reno.

(Sure glad I replaced my defective Windom balun with a 3000 watt balun this past summer..gonna need it now!)

Seriously...Thanks for the suggestions, gang! Tricks like those mentioned, are always welcomed!

Well, I forgot the spring washer even though I nearly
lost mine. Stuff like that is one reason I suggest working
in a shallow box. Its easy to miss some small part. The
washer is sometimes lubricated and the lubricant can make it
stick so that you don't realize its there until too late.

the old speaker is gone. it had other issues as well. I thought it would be easy to purchase a relatively cheap 5x7 replacement speaker. the newer speakers have the same bolt pattern but the MS-4 demands a speaker that is almost flat along top/bottom edges, across the mounting holes. modern speakers have an arc to the frame, and do not fit properly into a MS-4 case.

I'm sure I'll find something. I'm a little surprised that finding a replacement (that fits) would require this level of sleuthing!

Find another Drake MS-4. Maybe a really rusty scratched one. Use that speaker and then sell the old case w/o spkr. Or, could you fit in two 4 inch square replacement speakers onto the baffle? Mouser sells them and I use them all the time replacing them on All American Five receivers. Price is around $3.00 + for one. Put them in series observing polarity.

For the RV-4 situation I have used the Realistic 5" 40-1240D 4-Ohm speaker. A friend had a few old stock. It sounds fine - Both the original and the Realistic are round. Almost a perfect fit just a couple of edges of the speaker needed trimming.

Yes, of course, I thought of that, but what puzzled me was the lack of
a pattern, more of a shotgun approach.
The ones under the PA's make sense but the others are very random.

This rig does seem to give off more heat than my Heathkit HW100, which
I guess makes sense.

this has surely been discussed before, and yet, I've missed it if it has. have you ever noticed the small ~1/16" circular ring just above the 'R' (of R.L. Drake) at the bottom-center lip of the T4XC faceplate? it appears to be exactly where the phone-jack on the R4C resides. what is odd, is that I seem to remember noticing this same oddity on my R4B so many years ago, and wondering about it then. it looks to be a marker for a punch-hole but was not used.

any theories?

Daniel -

No theory... It was left over from the T-4X artwork which had the mic jack on the front panel. There is a matching clearance in the chassis behind it for the jack body.

fascinating. of course, the question begs .. was this an oversight, or that it wasn't worth the cost and efforts to change? it is odd, and I noticed that the Tony Mills panel replacements still incorporated the mark on the T4XB panel but removed it on the T4XC panel. now that too .. seems odd! the fact that Drake had to change the silkscreens for the newer model, leaves me puzzled as to why they didn't remove the marker at that time.

thanks for the quick response ...

I suspect that the mark was left with the intention of keeping the mic plug on the front panel, at least when the artwork was done.

They may have in fact printed the panels well in advance of the decision to move that jack to the side. Some liked it on the front, because it was much easier to pull the mic when you wanted to operate CW. But I think most didn't like it because it made getting to the knobs on either side more difficult.

I know that there was much discussion about its location on the T-4X, seems like you either loved it or hated it!

The new slanted skirt on the MAIN TUNING knob however, was universally approved. Many bought new skirts and/or knobs for their "A" line because the flat skirt was so hard to see in normal operation.

Probably guys who worked mainly CW didn't care, SSB only guys didn't like the knob interference, and those who went both ways liked having it on the front!!

After selling my c line twins a while back,I decided I want to find another set of twins. Looking for a drake 4 line.Iam not interested in the C series gear. Will consider R4,T4, also the A and B SERIES R&T. Iam not looking for perfect gear with perfect shinney copper,but also don't want gear with scales growing on the chassis. HAS to be NO SMOKE gear. the outside cosmetics need to be decent,not collector quality gear.I would like to find gear that isn't going to take hours of bench time to get up and running. Power supply can be either ac-3 or ac-4,will rebuild. Please no spray can restorations.
Let me know what you may have.
thanks

Joe -

I've been out of town for a few days. Been going through 350+ emails.!

I'm sure it's too late now, but you do NOT have to remove the front
panel to replace the meter "blue".

Simply remove the white painted shield behind the meter. Note carefully
which wire goes where on the meter, and be sure the insulating washers
are replaced correctly.

LOT's easier than pulling and replacing the front panel!

I looked and looked, but because of the nuts being varnished on, they wouldn't turn without turning the whole screw, and as there was no way to put a screwdriver on the other end...the panel had to come off. (I am talking about the meter, not the dial..the dial was easy...2 screws and it was off.

It wasn't hard..just took 30 minutes longer than what I wanted to spend! LOL. Sure looks nice though!

You haven't read to my amplifier question yet, I presume. I will have it here tomorrow....but I am still scratching my head. I suspect the L-4B is activated through the power supply connections..so if I want to use the amp with a non Drake radio, I may have to modify it somewhat...not real excited about doing that though.....then the amp is no longer 'pristine'.

3821. Re: [DrakeRadio] Drake Blue Filter History

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-13 19:03:01 UTC
From: Garey Barrell
Topic: 3780 Message: 3821

Joe -

I had forgotten about that. What you have to do is put a small screwdriver in "sideways" between the panel and sub-panel and fit it into the screw's slot. You can hold it that way enough to turn the nut with a nutdriver to remove the meter shield. Anyway, I saw the later message where you had successfully performed the surgery "your" way! :-)

The L-4B is controlled by the two pin connector on the rear panel that matches the one on the side of the AC-4. As designed, the AC-4 end is isolated from ground. The L-4B end has one side grounded, so there is no polarization required. Unfortunately, that two-pin plug must have been obsolete when it was selected, as they have ALWAYS been hard to find. They show up on eBay once in a while for $20 or more!! Drake sold them for $0.15..... Anyway, Drake eventually gave up as well, and marketed a little conversion kit that consisted of a small aluminum plate with an RCA phono jack in the middle, and two mounting holes that matched up with the original holes in the AC-4 and L-4B. I think John Kriner still has some of the 'kits', but I believe he wants $20 for those as well. Very simple to make one, if you have access to a metal shear and a hand drill. You could probably make one out of some aluminum strips from a hobby shop or hardware store, cut by scoring and bending and then file smooth.

To use with a non-Drake radio you just need to "polarize" the connector at the L-4B end, if using the two-pin one, since most other transmitters use an RCA phono jack, and key to ground. If the Linear "keys" when you connect it, just turn the two-pin connector "over".

Since you want to use it with both, I'd convert everything to RCA jacks and be done with it!!

HI,
Don't think so, but you can look as you wish. There are some spare switches out there and maybe someone will come to your rescue. Rumor has it that in or around 1982, there was a vendor at Dayton who had hundreds of NOS switches for sale. They were scarfed up by many, but some were passed by. Guess they trashed the rest? Who knows. If the on-off switch seized, then the cw-ssb is next. If you get it fixed, get a "soft start" for a delay in on-off. Helps the longevity (sp?).

Many have asked and seems no one volunteers, hence the article on wb4hfn. Mine works fine, and acutally as good as new after the refurb.

I am going to look at a number of switch innards and see what hope they hold. Never expected to find the exact physical switch, but having new innards will help. I have already taken mine apart and will start cleaning the contacts today with a Dremel tool and small file. It should be OK after that.

I still am going to call McGill, the original mfg., and see what they say. Doesn't hurt to ask and they may have some suggestions. Not too many 20A rocker around, for sure.

Garey, Joe,

I found that two subminature 3/32" phone plugs work quite well with the "vox relay" socket on the AC-4. They stick out about 1/8". I wired the tip and ring of each plug together for each wire. I used the type with a plastic shell that covers the threads of the base of the plug because the two shells will just touch.

I'll send a photo if anyone wants to see it.

Bill

Joe -

I had forgotten about that. What you have to do is put a small screwdriver in "sideways" between the panel and sub-panel and fit it into the screw's slot. You can hold it that way enough to turn the nut with a nutdriver to remove the meter shield. Anyway, I saw the later message where you had successfully performed the surgery "your" way! :-)

The L-4B is controlled by the two pin connector on the rear panel that matches the one on the side of the AC-4. As designed, the AC-4 end is isolated from ground. The L-4B end has one side grounded, so there is no polarization required. Unfortunately, that two-pin plug must have been obsolete when it was selected, as they have ALWAYS been hard to find. They show up on eBay once in a while for $20 or more!! Drake sold them for $0.15..... Anyway, Drake eventually gave up as well, and marketed a little conversion kit that consisted of a small aluminum plate with an RCA phono jack in the middle, and two mounting holes that matched up with the original holes in the AC-4 and L-4B. I think John Kriner still has some of the 'kits', but I believe he wants $20 for those as well. Very simple to make one, if you have access to a metal shear and a hand drill. You could probably make one out of some aluminum strips from a hobby shop or hardware store, cut by scoring and bending and then file smooth.

To use with a non-Drake radio you just need to "polarize" the connector at the L-4B end, if using the two-pin one, since most other transmitters use an RCA phono jack, and key to ground. If the Linear "keys" when you connect it, just turn the two-pin connector "over".

Since you want to use it with both, I'd convert everything to RCA jacks
and be done with it!!

There have been many homebrew versions of that stupid connector, but
yours is a new one!

The pins are 0.093" dia, and on 0.350" centers. I have used 3/32" dia
tubing from the hobby shop, and molded the back with RTV.

I still say the RCA jack is the best answer! :-)

Garey,

The RCA jack might be the best long term solution. I had read about your 3/32" tubing solution and realized that I had some sub-mini (3/32") phone plugs in the junkbox so I thought I might give it a try. Since it seems to work well, I thought I might share it with other Drakians.

3833. TR-4 Finals and driver (cross posted)

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-14 20:41:20 UTC
From: Forrest Plumstead
Topic: 3833 Message: 3833

The boys at Chesapeake Amateur Radio Service (CARS - W4CAR) did it again. When I lived in Virginia, one of the members loaned me an Icom 730, which I had to return when I moved back to San Antonio.

However they gave me a Drake TR-4 which needed some work before I left. They tried to trouble shoot it before I left. The major problem is no modulation. They traced mod from the mike to the filters, but ran out of time. The is also a problem with a sticky loading cap.

Well this morning a package arrived from the club president who sent me a matched set of finals and the Driver tube. Here's my question. Do any of the list members live in San Antonio and have a good test bench, and time on their hands, who can help me bring this radio back to its former glory?

Thanks for any help

Very good. If you talk to McGill, tell them there is demand for the rear bakelite case that houses the contacts, as well as the rocker arms. Most of the time the two exterior switches are ok. The arms and contacts are where the potential damage exists. Good luck on your repair. I'm sure it will work like new. BTW, a good time to replace the two panel lights while everything is disassembled. The article on wb4hfn.com lists a couple sources for original replacements.

From: Garey Barrell
Topic: 3836 Message: 3836

The time has come to begin lightening the load for the next move.

This is a TR-7 in beautiful condition, (original non-sticky cabinet,)
perfect front panel, and a PS-7 the same. No accessories aside from a
300 Hz CW filter.

The TR-7 is s/n 4036, full power out on all bands, 140 - 120 - 110W.
All controls, switches, etc. work as they should.

This is an excellent example of this fine transceiver.

Topic: 3837 Message: 3837

I was not able to find a xtal xref chart in Garey's CD, nor in the other information I have. Which xtals are for which bands (schematic is confusing), it looks like 80M and 20M have no xtal.

What is the one next to the PTO? Wish I had a chassis top view parts ID to refer to.

While I have your attention, I have read opposing views on the orientation of an added PA fan. I usually direct the air 'IN' to the compartment if the fan is strictly for the PA tubes. There is no room for a fan on top due to my desk shelving so I always attach the fan to the back.

Dick,

For 80m and 20m, the VFO signal bypass the premixer. For 40m, 15m, and 10m, the VFO and the crystal osc hetrodyne in the premixer.
40m uses a 21.5 mHz xtal, 15m uses a 35.5 Mhz xtal, and the 10m bands use 42.5, 43.0, and 43.6 MHz xtals. I'd have to open mine up (which I can't do right now) to tell their location in the xtal holder. (BTW, this is described in the theory of operation section of the manual if you need it for further reference).

Subject: [Drake] TR4C crystal ID

I was not able to find a xtal xref chart in Garey's CD, nor in the other information I have. Which xtals are for which bands (schematic is confusing), it looks like 80M and 20M have no xtal.

What is the one next to the PTO? Wish I had a chassis top view parts ID to refer to.

While I have your attention, I have read opposing views on the orientation of an added PA fan. I usually direct the air 'IN' to the compartment if the fan is strictly for the PA tubes. There is no room for a fan on top due to my desk shelving so I always attach the fan to the back.

"OUT" is the correct orientation for a single cooling fan on just about anything. "OUT" cools the whole box, "IN" cools what it is pointed at, but pushes the warm air around inside the rest of the box.

Hi JB

As I noted this message is cross posted. Drake Group is the other group. I have been a member for a while. While I am sure that when I am ready for it, I will be needing all the help I can get. My major problem right now is lack of troubleshooting equipment. None of what little bit of instruments that I have are suitable for the problem at hand Modulation). That is why I am hoping that a local San Antonio ham might have the equipment so that I can restore this fine radio.

BTW the tubes are 6jb6.

Just curious, did you re-lubricate the switch? I've been following the thread with interest, because I have one each L-4B and L-7. The article on wb4hfn.com is great work, and I'm one of those guys that likes to take things apart that aren't necessarily intended to be taken apart. But I did notice that the article in question did not mention re-lubricating the switch.

Another point that helps preserve the life of these gadgets, with or without a soft-start, is NEVER power up the amp with the switch in the SSB position. The inrush is less in the CW postion.

Also, there is the Drakelist reflector, at http://www.zerobeat.net/drakelist/ .
It is perhaps the oldest and most active, and has a searchable archive that
contains answers to a lot of questions. Note that there is an online Drakelist
forum acessible from the same page, it is NOT the same as the Drakelist email
reflector.

Hello

I'm not sure which xtals you are discussing. As far as I am aware the xtal sockets on the top chassis are for optional additional bands.

The xtals under the chassis are for the normal bands and according to my handbook their position depends on the serial No. of the xmitter.

With serial No's up to and including 20856 they are mounted as follows when looking under the chassis from the facia panel end (front)

39.6 (nearest the facia)

25.1

32.1

18.1

14.6

With serial No's 20857 and above they are mounted directly the opposite i.e. the 14.6 is mounted nearest the facia and so on.

Hope this is what you are talking about.

Vic -

This is correct for the T-4XC, but NOT for the TR-4C! :-)

The crystals for the TR-4C are on top of the chassis, just "behind and under" the meter. It came with three crystals, in sockets 1, 2 and 4, counting from the front left. Socket 3 is for a 42.5 MHz crystal for the bottom of 10M (28.0 to 28.6), and socket 5 is for the 43.6 MHz crystal for the top of 10M (29.1 - 29.7 MHz), and these were optional. The included crystals are:

1 - 21.5 MHz for 40M

2 - 35.5 MHz for 15M

4 - 43.0 MHz for the middle of 10M (28.5 - 29.1MHz)

No, I did not lubricate it. The little spring enclosures look to be rubber, so maybe they provide some sort of lubrication by being smooth.

I want to mention the mod on the wb4hfn website is for a L4B and shows the switch being easily removed, as the screws holding down the switch are shown easily assessable from the front. But in the L-7 case, only one screw is easy to get at. The other takes a fair amount of gyration to get the screw back in its hole. A magnetic screwdriver will help here.

Jim,
Since I wrote the switch article, I'd be remiss not to respond. Yes, after cleaning up, put a bit of lube on the plungers. Probably should have included that in the article. Just a dab on side of each of the two plungers....not too much. And I don't see a need for much at all on the tip of the plunger. Just a tiny bit. They are stainless steel, and cause the rocker arm to move from one contact to the other. So.....just so they slide in and out good with the spring. Also check the springs for damage, and replace as needed. Then,....good as new.

The majority of failures are seizure of the contacts, ie: stuck on. And on the SSB-CW, it is most likely stuck in the SSB position. Most all of these can be repaired. A good thing, since few NOS switches are to be found.

Thanks Bill, boy do I feel stupid. I just overlooked that part of the manual. I also found the ID of the xtal next to the PTO by rescanning Garey's CD until I found a top view. I guess if I had given it more thought I would have realized it was for the calibrator since it is wired to V5. Some days it doesn't pay to get out of bed.

Dick,

For 80m and 20m, the VFO signal bypass the premixer. For 40m, 15m, and 10m, the VFO and the crystal osc hetrodyne in the premixer.
40m uses a 21.5 mHz xtal, 15m uses a 35.5 Mhz xtal, and the 10m bands use 42.5, 43.0, and 43.6 MHz xtals. I'd have to open mine up (which I can't do right now) to tell their location in the xtal holder. (BTW, this is described in the theory of operation section of the manual if you need it for further reference).

3849. TR4C weak audio and poor sensitivity

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-16 23:26:53 UTC
From: Dick KF4NS
Topic: 3849 Message: 3849

During the restoration I discovered what may be my worst nightmare.
The sensitivity and weak audio changes from band to band when I switch
sidebands. That to me says it is likely to be one of the filters.

Example: on 20M the trouble is on USB and on 15M it switches to LSB,
in other words the trouble is always when the sideband switch is in
the X position.

All tubes have been tested and shorted/weak tubes replaces with new
ones (pretested).

The contacts of all switches have been cleaned and the sideband switch
tested for continuity.

The 9mhz osc was adjusted for zero beat with C130 injecting a
calibrated signal to grid 1 of V12.

I have no idea if it may be an alignment problem caused by changing
several tubes so please clue me in if that would cause this trouble.

3852. Fan for T4-XB

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-18 02:55:47 UTC
From: Richard Knoppow
Topic: 3852 Message: 3852

I decided that I should rig a fan to cool the finals.
I was lucky in finding a new 115VAC small fan at the surplus store for $5 and rigged it with grills on both sides to keep my fingers out, and put a wrap of foam weather stripping around the edges. The weatherstripping serves a dual purpose: it seals the fan to the cabinet, and it provides a bit of isolation. The foam is stuck to the fan but just sits on the cabinet. I rigged it to suck the hot air out and it seems quite effective. I was lucky in getting a fan that does not make much noise. Its rigged with a switch in the line cord. The cost of the fan, even a more expensive one, is a lot less than the cost of replacing the tubes so I think its an economy. I am tempted to fix up another one for the R-4B.

Hi David,

Thanks for writing, I had fogotten who wrote the article. No excuse, I could have gone and looked... :) Like I said, great work! I have taken apart all sorts of stuff, including switches, that weren't supposed to be taken apart and fixed, so your article felt like deja-vu.

You might want to update Ron with what you wrote below. Good info. THANKS!

3854. FS: 455 kHz Filter Partial Kit

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-19 21:37:16 UTC
From: Bry Carling
Topic: 3854 Message: 3854

For Sale: 455 kHz Filter Partial Kit

This is suitable for a 250 Hz bandwidth CW filter. Has 60 dB
rejection outside the pass band. Connect right after the last i.f. and
before the detector in almost any receiver design.
Two pole filter design using tubes - typically like a
6AK5 and 12AX7. Can also be adapted for use with a modern
transistor circuit.

Comes with all instructions, schemtic, complete article and
two 455 kHz hc6u crystals.

Two sockets available for an additional $5.00 with this kit.

I currently have eight of these kits left, and they are available for
$32.00 each plus shipping.

I mounted a 12VDC 80ma muffin fan from a blown PC power supply to the rear of the final cage on my T4XC. I used two long bolts, washers, and nuts fed. The bots are fed through 2 holes on the rear of the final cage. No drilling required.

The power for the fan is obtained through a half wave rectifier powered by the filament supply as it enters the transmitter. The diode is a simple 1N4007 and the filter capacitor is an 8ufd 50VDC cap and the fan runs at about 3/4 speed. The fan comes on when the AC4 is turned on and its very quiet.

I simply used a 117VAC fan, and some good 3M Clear mounting tape, to the top of the tank, and plug it in, when I fire up the transmitter. It keeps the finals at a nice, stable temp, and have had no issues. It is easily removable, with no damage to the case. Pulling the air out the top of the case, seems to do the job well.

Does anyone know of a source for the dial windows i.e., the plexiglass with the red line for the r4 series, especially for the r4b?

I have searched the resources I could find, but to no avail.

Thanks,
Ed

A source of thin plastic sheet would be welcome. I can't find any locally, I've tried a couple of hardware stores, a couple of art supply stores, a plastic store; no luck. They have thicker stuff. I don't need to replace a Drake window but do need to make some indicators for other stuff, for instance a Hallicrafters Sky Buddy.

Richard -

I found two 8" x 10" x 1/16" sheets at my local Michael's craft shop.
Company called Gallery Glass, "Styrene Blanks". Plaid Enterprises,
Norcross, GA. Don't recall what it cost, but I'm sure in the $2-5 range

I was able to find some 1/16" plastic. I wanted
something a bit thinner for the Hallicrafters set although
this stuff will do. I guess the dial window in the Drake
_is_ thicker material and would have to be.

Richard -

I have considered the clear plastic used over some office products. I bought a stack of CD labels that was about an inch thick, enclosed in clear plastic, and punched to hang on a pegboard. It had two 'sheets' of 1/32" or even 1/64" thick on either side! You know the stuff that you're sure is going to cut a finger off before you are able to wrestle the product out of the package! :-) It's a 'little' flexible, but pretty good.

Depending upon size, you might be able to use a piece cut from a CD box. Nice and clear, but perhaps too thick still.

Would there be enough "real estate" on one of the clear protector disks that
are on the ends of the CD/DVD spindle packages to work? That's some interesting
plastic. I recently made a repro dial for a Swan-manufactured radio from a pair
of them. It looks good. They could be used for lots of things.

You may have tried it but how about the clear sheet protectors
like are used in binders or to protect a cover sheet?

McMaster-Carr sells 12" square by 1/16" thick sheets of clear
polycarbonate. ("Lexan" is a trade name for a similar product)
This material is easy to cut and drill and is inexpensive.
McMaster-Carr accepts small orders.

Morning to all on the list from a very sunny England.

Hoping that soneone out there can give me a definitive answer regarding what should be the manufacturer original cabinet paint finish for a vintage Drake RV-7 external PTO.

The background to my query is that I have just purchased an RV-7, described by the seller as being in 'mint' condition. I paid 'top dollar' for it based on his description. Having now taken delivery and sat it alongside by late serial number TR-7, I was very disappointed to note that the colour and texture of the paint on the RV-7 was a mile away from that on the transceiver.

The paint colour of the RV-7 I have received is a very blue-grey (possibly similar to that on the 4-series Drake equipment, if memory serves, though I have never owned any) and a pretty smooth to the touch texture. On the transceiver I have, the paint colour is a dark grey, toward black, and a very fine crackle texture.

I recall that early TR-7 had some sort of 'sticky' paint issue, resulting in many of them being resprayed by their owners. I am wondering whether the same might be the history of this RV-7.

The RV-7 came in its original Drake box and in all other respects is as described. The service tag in the box reads: Serial 488, with a date of 9 August 1978.

Any and all help appreciated.

Regards,

Mark.

Mark -

My answer is far from "definitive", but I believe what you have is just a very early example of the RV-7, which first came out mid-summer of 1978. I have never seen the so-called "sticky" paint in the wild. I have a TR-7, 1200 series, that has a color as you describe, i.e., smooth, very dark gray closer to black. Whether this was once "sticky", I can't say. Perhaps yours is just one that didn't/hasn't gone sticky. I have a TR-7 9000, and RV-7 2600 which are the gray, textured finish you describe, and which I believe is the most prevalent paint scheme.

There were aftermarket covers sold by Drake, possibly to fix the sticky issue, that were a black wrinkle. This was the finish that was being used on their commercial TV equipment at the time. But they have a definite 'wrinkle' finish.

Garey,

You are either very lucky, or live a sheltered life. :) Probably half of what I see out here in flyover country is sticky paint. The amount of "stickyness" does seem to vary, so perhaps the problem lay in variations in the paint formulation or application technique. I also have an old DIgitec frequency counter that has sticky paint, although a different color.

FWIW, the oven cleaner procedure published on the WB4HFN web site works very well for eliminating the "stickyness".

Thanks for all the suggetions, I am talking about the piece with the red line that goes behind the fron panel with the red lin and the red pin inside.....I was wondering if anyone made them.....I have cut some from plexiglass and they look good, looking for a good way to make a crisp red line...I have some auto pinstriping I have bought and looks pretty good, but not that good. I dont know how to make a nice red line, may try a sign painter and have him do a bunch to make it worth it. Was actually wondering if anyone was selling repo's of this item, not the actual dial iwth numbers.

Hi Garey,

No I am talking about the plexiglass rectangular window with the red line....I broke mine when trying to replace the red pin. Wonder if anyone is making them...I have cut some plexiglass here, routed out the slide and drilled the hole in about 10 pieces, but the crisp red line eludes me...I tried some auto pinspriping...and it looks good, though not perfect.
Wondering if guys knew of someone selling one with a nice red line.

If it were me, I would go to a leather shop and look for one of their small, very sharp, 'V' gouges, then using a straight edge, practice making a very small V shaped gouge. Then using some good red aircraft enamel, 'flow' it into the V, and let it dry.

Ed -

OK. Donnie, WA9TGT, used to make them, but he got out of the business.
Might be worth an email to ask how he did it.

Since you seem to have a router, I'd use a small end mill to make the
line, and then fill it with either acrylic paint or possibly the red
engraving fill stick that AES (used?) to have. The acrylic works pretty
well since you can fill and then wipe the surface for a nice sharp edge.

That would work, but the 'original' had the groove and the paint fill on
the inside. So you need a 'flat bottomed' groove.

I didn't look that closely when I took mine apart..but...I think the V with enamel, viewed from the back, would still look pretty good. I would do some experimenting to see. The biggest problem I think anyone would encounter, would be making the groove without chipping the edges..plexi has a tendency to do that. I wonder if working with Lexan would be any easier....more expensive but not as brittle.

Just a thought, would chart tape, like they use on the dry erase boards work? It comes in 1/16" width and comes in red. I've used that on dry erase boards and lasts forever.

Texture, schmexture... As long as there is paint there, I'm happy. I rarely see the case when the radio is in the operating position and being used... :)

Bill -

There are several differences.

1. The L-4 had 3-400Z tubes while the L-4B had the "new" 3-500Z tubes

2. The L-4B added a front panel control to adjust ALC level, with a
push-pull switch to STANDBY the amp.

3. The L-4 had a relative power meter and the L-4B had a Bruene
wattmeter with 300 and 3000 FWD and 300 REF.

Nope, not a one. The closest thing I have is a Heath IM-16 FETVM that I bought new that has a 'sticky' beige paint. It's 'thick' and became sticky, almost like it was originally a thick coat of paint that was almost dry when it was applied. I'll have to try the oven cleaner on it! It's a nice BIG meter. Of course I have three IM-18s, two IM-11s and two IM-28s, but that's a different problem. I just can't leave them there on the ground at hamfests. Plus they are nice for voltage readings in the 4 Series as long as some clown hasn't done the "move the 1M probe resistor inside" modification that's floating around the internet. Gee, ya think there was a reason the Heath engineers (and others) went to all the trouble to build a switching probe? Nahh, this is "an improvement". Rant off.....

3888. Re: L-4 vs. L-4B

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-27 14:12:50 UTC
From: David & Chris Drake
Topic: 3884 Message: 3888

Hi, some early L4b's were shipped with 3-400z's, then later, exclusively 3-500z's
All L-4's were 3-400z's and many were upgraded to 3-500's later.
You may want to go to the Drake Museum site, or to Ron Baker's site for more detailed information
including pictures and manuals.
http://www.dproducts.be/DRAKE_MUSEUM/
www.wb4hfn.com

Both of the above sites are excellent Drake references for all products.
Click on both and then save them to your "Drake" favorites folder !!

Here's a pic of an L-4 from the museum site:
http://www.dproducts.be/DRAKE_MUSEUM/l-4.htm

Note the missing standby/AGC control. The AGC control was on the back. Also of note is the meter changes from L4 to L4B, as well as the meter switch. As I remember, there were no changes to the power supply. Basically the same, but the L4B is preferred.

The L4B came in two cosmetic styles, the earlier one had a silver trim ring (unpainted aluminum) around the dark painted area. This was a match to the R4 thru R4B series trim. When the "C" line came out, the entire area was painted and was a match to the C line cosmetics.

Others may wish to add, but I believe I've covered the major items of difference.

Have fun,
David

Working on my TR4. It has 2 bad tubes at the moment; V7 & V12. I'm obtaining replacements this week.

My question today is what number tube should be in V5's position? My op. manual claims that it should be a 12BA6. I have on my chassis the marking of what appears to be 6BA6. But, it's nearly worn off. I have in there a functioning 6BA6. But to complicate matters worse, I found a website that claims it should be a 6BZ6.
What should be in there? Thank you for any help you can provide.

The rig only works on 80m, both Rx & Tx are great. At least 110W output. No other band functons at all.
Please help.

Bob -

It's amazing that you have that many 'bad' tubes..... I've worked on a LOT of Drake radios and I can't recall ever finding more than three bad tubes in a single radio. How are you determining that they are 'bad'??

Today's question: First off, there were eight versions of the TR-4. Your manual is for one of the first four versions, which DID use a 12BA6 for V5. Yours is version five (5), and is the only version with a 6BA6 at V5. Version 6 and up all used a 6BZ6 at V5. So. You have the right radio, wrong schematic! You obviously need my CD! :-)

The good news here is that either tube will work fine at V5, which is the Crystal Calibrator. The 6BZ6 is a little 'hotter' tube, so will probably last a little longer, and have a little higher output on 10M. Facts: Either will work, if your Crystal Calibrator is working you probably don't need a new one. If it was my radio, I'd replace it (if necessary) with a 6BZ6, and let the next guy wonder why it has the 'wrong' tube in it! :-)

The correct schematic for your unit will have the number 466827500 bottom center under the title.

Does your radio NOT work on 20M?

3892. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-27 20:46:34 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 3892

All group memebers are welcome to post here on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others (what you put into this group you will get back so participate if you have a chance). Although we would like to focus on Drake Radio subject matter any Ham Radio subject matter is allowed. This includes any QST's of events or hamfests, especially if Drake radios are included

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our groups home page, as well as links to Drake information or your homepage.
Thanks to all members for your particapation.

Thank you Garey for your response.
I have tested the tubes using a large in-store type Radio Shack tester from the 60's/70's.
You can see it on my QRZ bio page.
One of the new 12BA6 tubes that I received tested very good. Upon re-trying my old tube, that same test position shows 'bad'. So, I'm convinced the tester is functioning.
No, the rig doesn't work on 20m. The Xtal cal. works though.
I suppose I better get that CD from you. :)

Bob -

That's unusual, working on 80 but not 20. A part of the circuit (Band Oscillator and Premixer) is not used on 80 AND 20. The 9 MHz Carrier Oscillator is mixed with the 5 MHz PTO, giving 80M with the Mixer's difference output, and 20M with the sum output.

That type of tester is a simple emission test, which tells little more than that the filament is good. Keep in mind that it's primary purpose in Radio Shack was to sell Radio Shack tubes! :-) The only real test is if it works in the radio. It's best to keep a set of spare tubes that have been 'tested' by putting them one at a time into a working radio. If it still works, remove that tube and put it back in the box. Then put the original tube back in. DO NOT replace ALL the tubes at one shot.

Are all the tubes lit (hot)? There are a couple of series/parallel heater strings in that TR-4, kinda like the old Christmas tree lights, one goes out, they all go out.

I'll have to look at the circuit to see if I can find something that would allow it to work on 80 but not 20. I would suggest that while you're waiting for tubes that you go through the entire radio with a screwdriver and check each of the sheet metal screws that hold things like tube sockets and terminal strips to the chassis. Loosen each one just slightly and then retighten firmly. This will fix a "lot" of strange and/or intermittent problems. I'd also suggest that you get a bottle of CAIG DeoxiT D100L and use the needle to apply just a drop to each switch tag. If you really want to go first class, get a can of CAIG FaderLube and spray it inside each pot. These two chemicals will save a bunch of time troubleshooting dirt!

I think you'd find the CD very helpful, it has the correct schematic and other info for your version.

Post here if we can help!

I want to re-enforce this. I chased my tail over several
T$ problems until I got Garey's CD. Among other things he
has good photos of the innards that show where things are
and how they should be wired. I had a problem with not being
able to attain a good carrier null. After looking at the
pictures in Garey's CD I found that the wiring to the
balanced modulator was wrong. OK according to the schematic
but mechanically wrong and the difference in stray
capacitance was enough to upset things. He also has very
high res schematics that you can have printed out large
scale, they are _very_ helpful in tracing down circuits.
Unfortunately, some Drake schematics look like maps of the
Chicago freight yards, a large scale one plus a couple of
colored pencils will make a lot of stuff clear.

>I bought new that has a 'sticky' beige paint.

Give it time, you'll run actoss it sooner or later. It seems like most of the TR-7 I see around this part of the world are sticky. Accessories are maybe 50/50. Both of my RV-7 are sticky (I think, the spare is stored away in it's original box); the R-7A, MS-7, SP-75, and CS-7 indoor box are not. I've thought about eitehr repainting or acquiring one of the newer covers for the TR-7, but in the end, I just don't really care that much because I rarely see the cover when the radio is doing what it was meant to do. It's not a shelf queen, after all. :) Over 1000 Qs on 20 fone over field day on that radio.

I think my Heath freq counter may have the sticky paint, but I'd have to dig it out and look at it. It's the Nixie model, and is a collector's item of sorts - purchased at an employee auction, it still has the Hy-Gain Electronics asset tag attached.

>Plus they are nice for voltage
>readings in the 4 Series as long as some clown hasn't done the "move the
>1M probe resistor inside" modification that's floating around the
>internet. Gee, ya think there was a reason the Heath engineers (and
>others) went to all the trouble to build a switching probe? Nahh, this
>is "an improvement". Rant off.....

I have been suitably educated, Master Barrell. I have one of the (non-sticky) Heath VTVMs *somewhere*, I believe with the appropriate probe. I've been meaning to search it out, especially now that I have discovered that I have a Heath PK-3 RF probe for it (with the correct connector). I shortened the mile-long ground lead on the probe (Heath engineers didn't know EVERYTHING) and tested it, and it works fine. I had thought about doing that "mod", but didn't since I had the probe. Now that I know, I will not invoke the wrath of Barrell by sullying my VTVM with Philistine hacks. ;)

Joe,

perhaps it is just an odd coincidence, but I too, have been trying to buy Leo's MN-2000 for several weeks now. I email him with no reply, then, days later I email again and receive a 'yes, it's still for sale'. so, I go through the motions once again, and nothing. no response. it's one of the very few pre-purchase transactions that I have been suspicious about enough to reconsider.

based on your observations (as well as my own), this pursuit of Leo's MN-2000 is terminated. if Leo came through for you, enjoy your new Drake tuner!

by the way ... I'm still looking for a MN-2000 from a serious seller!

I have submitted two inquiries to Tony Mills at 4CFRONTPANELS for a RV4-C panel, with no response. perhaps he is on vacation or ham conventions, but I am surprised that no response had been forthcoming. still in business?

I recently purchased a nice RV4-C, arrived as advertised, except for the 1" dent in the panel, as if someone stuck their thumb in bread dough! the seller claims it wasn't there when it was shipped (it obviously was) ... sigh.

oh yes, anyone have a spare black screw for the Drake panels? mine has a 'replacement' that is 3X the size it should be. I'll pay, of course, for the part and shipping.

Daniel -

I don't know about Tony. I certainly hope is still making panels.

A possible hint on your panel dent. If the metal is not creased, you might try the old idea of applying a vise or C-clamp with wood 'bumpers' to the dent. Careful compression under heavy pressure can often make such a dent invisible, or at least minimize it. When you remove the panel, keep a sharp eye out for the small, black spacers between the panel and the chassis on each screw. Easy to lose, and not a common hardware item.

Ron, WB4HFN has "original" cabinet screws. Most are pretty chewed up by now, and all new ones sure look nice.

3900. Re: Drake RV-7 cabinet paint finish question

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-29 08:07:52 UTC
From: atlasstuff
Topic: 3872 Message: 3900

Thanks to Garey, Jim and Joe for responses re. my question.

If the paint finish is indeed original, then I shall certainly leave it as such, despite it not matching that of my transceiver.

I gave the Jones plug on the end of the cable attached to the RV-7 a good clean with some electrical contact cleaner on a cotton bud last night. That stopped the frequency instability problem I was having whenever the plug / cable was moved. The intermittent power problem has also gone away - I suspect that this too was related to dirty plug contacts.

Now a 'keeper'!

Regards,

Mark.

Bill -

The B-Line had the bright trim around the panels, and the C-Line was the no border version. Both were pretty common. The very early ones were painted, more like the 2-B and A-Line, and they went to what I think was more like heavy vinyl 'contact paper' sometime during the B-Line years.

3906. Re: [Drakelist] TR4C weak audio and poor sensitivity

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-06-30 22:01:55 UTC
From: Dick KF4NS
Topic: 3906 Message: 3906

Well guys, I found the trouble. I decided to try inserting a signal with my sig gen and started with the antenna jack, then went to the external antenna jack, then went to the fuse lamp socket (tested lamp removed) on the relay side, then to the T-9 side, VOILA! Good strong signal S9+5 at 50uv. I knew then that it had to be related to the relay. I pulled the 6EV7 relay tube V19 and it tested good. I substituted another 6EV7 and the trouble went away completely. I put the original tube back in and still no trouble !?? Socket was in good shape so it's a conundrum.

Hope it is not the T/R relay since I can see no way to remove the cover. Usually these relays are not used as a plugin so nothing to anchor down the base and rock the cover back and forth to pop it off.

Bottom line, the rig works great. Still no doubt that the LSB filter is bad. Adjusted C130 best I can. It will be good enough. Can't afford to buy the INRAD filter set. Will still scope it out at the CXR BAL and at the filters.

You never know with the contacts in tube sockets and tube pins. I had a 12AX7 that mysteriously would not work in a T-4XB but tested OK. I discovered that the problem happened when I had the tube in an extender to measure voltages. When I put the tube in the tube tester _on_ the extender, one side was nearly dead. The extender worked on all other tubes. The problem: corrosion on the tube pins. It happened that they made good contact with the tester socket and transmitter socket but not the extender socket. After wire brushing the tube pins the tube worked fine in the extender. So, it could still be a bit of corrosion on the tube pins and working the tube in the socket cleared it up. Try removing the tube scrubbing the pins with a fine wire brush or something else that will remove any corrosion and then putting a bit of contact cleaner on them and work the tube in the socket. This will help clean the socket. Probably never act up again.

From: Jim Shorney
Topic: 3909 Message: 3910

Ivan,

You will need to Google for the wire color codes for the Astatic. The TR-7 mic pinout is as follows:

1 - Audio (low level)
2 - PTT
3 - Ground (PTT and Audio common)
4 - Audio (high level, may not be avaiable in older TR-7)

If you are using the preamp in the Astatic, I would recommend using pin 4 for audio as opposed to pin 1. Pin 4 has a 470K resistor in series to reduce the level of high output mics, which would make it easier to properly adjust your Astatic preamp.

Of course, you don't really need that preamp, but that's a whole 'nother message. Also, the way that pre-amped mics are normally switched internally, you will not be able to use VOX unless you come up with a way to open the PTT line from the mic.

FWIW, I have used a Golden Eagle D-104 with the pre-amp disconnected and an additional 470K in series with the mic element, and received very good audio reports. I'm using a black Turner +3 (not a +3B) now. It matches the radio better from a visual standpoint, and I get very good reports on it as well (despite the fact that I detest pre-amped mics).

3911. Newbie in ham radio & Drake R4B

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-07-03 11:18:59 UTC
From: Gheorghe
Topic: 3911 Message: 3911

Greetings from Romania!

Im a newbie in ham radio and will soon start receiving with my first rx, a Drake R4B I got yesterday. I am hoping next week I will get some help from a friend to setup an antenna, until then Ill try to get familiar with the equipment.
I have a few basic questions and, if you'll be so kind to answer me, please bear in mind that I am hopeless with technical issues.
Anyway, even if I haven't used it in any way, I like the look and feel of this radio :)

1) I only have the R4b, no power source or loudspeaker. It has a power chord that can be plugged in the regular 220 V public service electric network. This is how we "tested" the radio when I got it the other day. Should I think of getting a dedicated power source for the radio, as an interface between it and the wall plug, or it is ok if I use it as is?

2) Any 4 ohm speaker would do the work? Should I pay any attention to any issue in particular?

3) Maybe this should've been the first: could you please point me to an online manual for the radio?

4) according to the guy that sold me the radio, the radio is fitted with these quartz filters:

quartz external (back of the radio)
26.1 MHz / 22.6 MHz / 20.6 MHz / 17.1 MHz / 15.6 MHz / 28.6 MHz / 32.6 MHz / 36.6 MHz.

quartz internal
14.6 MHz / 18.1 MHz / 25.1 MHz / 32.1 MHz / 39.6 MHz.

Is this a regular lineup?

Thanks and 73s

George

George -

1) No additional power source is necessary, but a loudspeaker IS unless you have headphones available. They will work without a speaker, but not as convenient.

2) There is a jack on the rear panel marked SPKR, and you need a "4 ohm" speaker with an "RCA Phono" plug. 4 ohm speakers can be difficult to find, so an 8 ohm would be ok if you are unable to get a 4 ohm. A 'standard' speaker is fine, a 6" x 9" oval or round. You do not need any special cones or fancy features!

3) A reasonable copy of the manual is at

<http://www.wb4hfn.com/DRAKE/DrakeManuals/R4B/Manual_R4B.htm>

There is an excellent document regarding the R-4B and Drake radios in general at

<http://www.zerobeat.net/drakelist/drakemod/drmodtoc.html>

4) The second 'internal' group of crystals provide coverage of the five of the six Amateur radio bands available when the receiver was built. There have been three bands added since then.

The first 'external' group of crystals are for additional coverage. You can determine the frequency band covered by each crystal by subtracting 11.1 from the listed frequency. This will tell you the frequency of the receiver when the dial is at '000'. Turning the dial will tune from that frequency to 500 kc higher, e.g., the first crystal in the first list of 26.1 Mc will allow you to tune from 26.1 - 11.1 = 15.0 Mc to 15.5 Mc. Choosing crystals and how to use them is shown in the manual.

One last item. You will need a 'shorted' RCA Phono plug inserted in the MUTE jack on the back panel for the Noise Blanker (NB) and Calibrator (Cal) positions of the FUNCTION switch to operate.

Welcome to the group!

Gerry,

I have he following available:

9.000 MHz
14.000 MHz
24.500 MHz
25.000 MHz
I'm still working on getting some at 14.5 MHz

I can ship these to Ireland.

Brian, AF4K

1. Crystals for 2B
Posted by: "gerrykav" gerryk777@... gerrykav
Date: Sat Jun 26, 2010 2:06 am ((PDT))

Hi... I am on the hunt for crystals for my 2B.
The frequencies I am looking for are...

25.6MHz
9MHz
23.4MHz
14.0MHz
14.5MHz

I am located in Ireland, but hopefully there will be someone that can ship
here...

From: Bry Carling
Topic: 3915 Message: 3915

FOR SALE:
I have several more groups of ham band crystals now available.

Most of these are around $2.00 or $3.00 each. Great for experimenting
and day to day operations on 75 through 10m bands.

Some of them are hc6u crystals. Most are the standard FT-243 types.

Example: QTY 7 - FT243 crystals for $14.00

Have a look here:
http://www.af4k.com/basementcrystals.htm

From: Dick KF4NS
Topic: 3917 Message: 3917

I plan on replacing the multi cap can with individual caps as part of the restoration, but first I have a couple questions.

1. Why is it there to begin with since the AC-4 has already filtered the 250V and why are there 3 different cap values? (I already replaced the 10mfd at 25V right at the pin8 connection of V19A with a 10 @ 50V)

2. The three values I have in mine are 60-20-10mfd at 250V so I planned on using a 100-33-22 @ 350V but would appreciate your input on these values I chose.

Dick -

The AC-4 was designed to drive the T-4X Series transmitters AND the TR-4 Series transceivers. I don't really KNOW, but I suspect that the AC-4 was designed for the T-4X, and the additional current and reduced ripple requirements of the receiver portion of the TR-4 drove the need for more filter capacitors. Also, since the DC-4 was used with the TR-4, with the possibility of long leads between the two could have driven the need for more power supply decoupling.

All models used the 60 - 20 - 10 Twist-Lok cap. The 20 uF was used to just decouple the main +250V at the input to the TR-4. The 60 uF and 10 uF were both used to further decouple the 245V and 235V supply busses for the low-level IF and AF stages.

Electrolytic caps available when the TR-4 was designed and built, were rated at D C Working Volts (DCWV), not as a maximum. The capacitance and voltage values you have selected will work just fine. Tom at HayseedHamfest.com has drop-in replacements which make for a much neater job. It's pretty crowded under the chassis.

Hi Dick,

1) I haven't measured the length of the cable on my AC-4 but I would guess its about 2 to 2.5 ft. Without the multi-cap can, the 260V supply terminal would see twice the AC-4 cable length between the 260V terminal and the chassis ground (i.e a wire from the 260V source in the supply to the terminal in the radio and another wire between the supply's ground and the radio's ground). Ideally you want the voltage source terminals in the chassis to present a good AC ground between the terminal at the radio's chassis. At RF going through 4 or 5 feet of cable might not make for a good ground. Adding the caps on the chassis I suspect is a solution for this. There is a series resistor from the 260V supply that drops it down to 250V if I remember the schematic. Adding a cap here does the same - making a good RF ground.

The amount of capacitance you need depends on the expected load and the amount of ripple you can accept. As a general rule, increasing the capacitance decreases the ripple but will increase the peak diode current during the time that the supply diodes are forwarded biased. I think the values you have will be fine.

Just my guesses as to why it was done this way.

Bill

The basic point is sound, but electrolytic caps do not make RF grounds. They
are there mainly for filtering and decoupling at AC line and audio frequencies.
Smaller caps, usually disc ceramic, across the same points take care of any RF
that might wander by.

I've been reading my notes on R4C alignment, and found the step of adding two resistors to 150V and ground, to separate wafers on the bandswitch. I don't have my schematics with me (vacationing in Canada). what is the purpose of this?

secondly, I noted that when using the T4XC and R4C slaved, that the CW sidetone is diabled when the tuning mode is set to 'separate'. why? it seems a worthy feature to have CW sidetone on all modes. 'separate, rcvr, xmit'.

Jim -

Agreed. I think the original intent was to decouple the power busses from possible noise pickup on the potentially long power leads from a DC-4 supply, and of course to provide a good low impedance power source inside the radio. They serve a similar purpose with the AC-4, but in this case they also improve ripple under the heavier current loads of the TR-4 over the T-4X, plus the decoupling and additional ripple reduction for the low level AF and IF stages. A good idea when the supply is 'remote' to provide a low impedance AC point inside the radio. The T-4X has C129 internal for the same reason.

You can safely disregard the 'alignment loads' called out in the manual. I think the original intent was to detune T4 primary and T3 while adjusting the INJ trimmer caps, possibly to simulate the loading of the INJ cable? The best procedure is to adjust the INJ trimmers in both units with the two cabled together, but of course Drake couldn't do that at manufacture since they were sold separately. Anyway, I have heard from several 'knowledgeable' sources that Drake quit using the loads as well.

I may be mistaken, but I believe the SIDETONE IS present even in SEPARATE. It's too late for me to attack it tonight, but I'll look at the schematic tomorrow. Perhaps someone else knows the answer and can clear it up.

What do you want, a DX machine or a casual QSO machine? The Sure 444 variants provide an excellent, natural 'dynamic mic' sound suitable for casual QSOs and rag chewing. An un-amplified D-104, Turner 254HC, EV 729, or other ceramic mic will provide a "crisper" response that works well for DXing and contesting. The unexpected surprise of my collection in the ceramic category is the Turner +3, which amounts to being a Drake 7075 with a built in compressor amp. Or, more accurately, the Drake 7075 is a rebadged Turner +3 without the compressor amp. I don't like amplified mics as a general rule, but the +3 has garnered such good reports that I've been using it on my TR-7 lately. I may yet bypass the amplifier and essentially make it a Drake 7075, who knows? The rare Drake 729SRD is a rebadged EV 729.

http://www.dproducts.be/drake_museum/nouvellepage4.htm

I find my best deals on mics at local hamfests, flea markets, and sometimes garage sales. All of the above, except the Drake rebadged versions, I have found that way in the $10-25 range.

Keep in mind that the D-104 head was around long before CBers discovered them, and was available with various pre-T-UG8 stands and mounts. :)

To be honest, I'm looking for a ragchew mic. I'll probably just put the thing on 3820 and forget it (With an occasional trip to the CW portion of the band for nostalgia). There are a group of friends up in PA, that I like to chat with there.

Thanks for the insight, it's definitely helpful. Maybe I'll check around at the next Hamfest, which is only a few weeks away.

Has anyone used this device on a Drake to reduce the white noise?

I have a West Mountain DSP speaker on my TS-2000 and a Heil DSP speaker on my FT-857D. They do a good job of reducing the extremely high background noise level I have at my location. (20 over S9).

I wonder of the JPS NTR-1 is any good at that. Fellow in New Jersey named Steve Torma has a couple for sale, and as I have a couple B Line radios I would like to use but can't due to the high noise level.....

Hello all
Trying to get a couple of parts:-
1. 1.5mhz CW filter for R-4C
2. Brushed aluminium disc that fits into the centre of one of the main (large)tuning knobs of the MN-7.
Tried this side of the pond with no joy.
Any help appreciated.

Hi Dave W5DMT,

I finally got my TR-4 operational a few weeks ago (thanks to Garey and others, but especially Jeff Covelli who refurbished the TR-4).
Found that my original antenna was the culprit in a serious RF-feedback problem. Nobody's ideas (locally) fixed it, so I ended up erecting a new antenna (folded dipole). RF-Feedback gone, and wow does the TR-4 work great. The guy that sold me the radio (and RV-3 and AC-4) also gave me a Shure 450, which had been dropped and it broke at the neck. Used crazy glue on it, and have found excellent voice reports.

I hope you find a mic that suits you, the radio shines with several mics. Suggestions from many folks on this SIG are all good <grin>.

Have fun and good luck!

Unless the C series is very much different from the B
the sidetone is certainly there in "Separate".
Also, I followed Garey's advise in tuning up my R-4B
without the loads and it worked fine. I use it with a T-4XB.

From: arsnf7z
Topic: 3936 Message: 3936

just an observation ... I noticed that using the 'audio' test to align the 9Mhz oscillator doesn't really illuminate how the filters are matched. there is a +6db difference between the lower and upper sideband filters, the LSB filter showing far greater loss. I just bought a new Tektronix Arbitrary Waveform Generator which should shed some light on the gain differences, perhaps due to filter-alignment though I doubt it. anyone else see this much differential loss between sidebands?

I am really impressed with the TR4C. it outperforms my R4C, slightly, it's that hot, but the Drake implementation of AM is really sad. that's why I also have a T4XC!

Here are some general notes on microphones: The audio quality of transmitters like the Drakes is primarily determined by the sideband filters both as to bandwidth and to responce within the band due to any ripple. Drake uses rather narrow band filters with very steep skirts. These concentrate the transmitted energy in the band of audio frequencies that carries speech intelligence. Much research was done on speech intelligibility by Bell Telephone Laboratories over a long period of time. In fact much of the research in speech and hearing was done at Bell Labs for obvious reasons. One objective was to determine the minimum bandwidth necessary for intellible speech. The Labs found that bandwidth could be severely limited but that if not enough low end was transmitted speech did not sound natural, that was am important consideration for the telephone system since subscribers would not accept unnatural sounding speech. For military purposes the bandwidth can be more severely limited. In fact, some Russian research showed that speech would remain intelligible even when so stringently limited that individual voices could not be recognized. If the energy distribution in speech is measured it will be found that in male speech and in European languages, the bulk of the energy is below about 500 hz but that the contribution to articulation, that is the understandability, of speech of this range is negligible. Intelligence is carried mostly by frequencies between about 1000 hz and

about 3000 hz. The Bell System research found that a bandwidth of about 2500 hz was sufficient to provide speech which had good articulation but remained natural sounding. Their range was from about 250hz to about 2750hz.
Noise has a strong influence on articulation and the effect of bandwidth. Under quiet conditions unfiltered, wide frequency range, speech has the best articulation; under noisy conditions speech wich is band limited and which is filtered to accentuate the range of frequencies which carry intelligence (1000khz to 3000khz) will be much more understandable than wide-range speech. So, for best articulation under noisy conditions its best to shape the speech spectrum to accentuate the mid-highs and attenuate low frequencies. Since the power in speech is mostly concentrated in the lower frequencies attenuating them with regard to the higher ones also has the effect of increasing available power for the intelligibilty range.
Microphones meant for high intelligibility under noisy conditions usually have some sort of frequency discrimination as noted above. Typically, "communication" microphones have limited low and very high frequencies and are built so that they have a rising responce curve between about 500 hz and about 300 hz often with a peak at about 2500 hz. Where the transmission system has no other filtering this can make a substantial difference in the understandability of the speech in noise. Where there is some discrimination already in the system such additional filtering must be used with some care. Typically, in transmitters such as the Drake line, only bandwidth filtering is used. There is some discrimination in the audio amplifier, mainly to attenuate the low end before filtering. Usually, this will help reduce intermodulation distortion but is not enoug to cause problems if a rising responce mic is used.
In fact, the difference in received quality due to microphone characteristics will be less than might be expected from listening to the microphone on a flat amplifier. However, the rising characteristic within the transmitted pass-band will still help to concentrate transmitted energy in the intelligence range especially in the presense of noise.
Amplitude processing:
Many transmitters have some sort of amplitude processing; either compressors, peak limiters, or peak clippers. All of these are for increasing the level of the average power level in speech in comparison to the peak level. Most transmission systems are peak limited, even digital ones. Because, in normal speech, the ratio of peak to average is very high the power available to carry intelligence is quite limited unless the speech waveform is

modified so that the ratio is increased. Probably the most effective means of processing for the purpose of increasing the intelligibility in the presense of noise is peak clipping. This must be done with the aid of spectrum shaping. The simplest method is to put the speech through a differentiator, clip it, and then put it through an integrator. While the terms differentiator and integrator suggest something elaborate they are in fact only simple 6db/octave RC or LC filters, high pass before clipping and low pass after clipping. In research done in the late 1940's J.C. Licklidder found that _infinite_ clipping could be used without destroying the intelligibility of speech, provided that the speech was processed as above. Under noisy conditions the clipped speech had better intelligibility than unprocessed speech but not under quiet conditions although the loss of intelligibility there was not severe. For typical ham transmitting conditions about 6db of clipping is sufficient and generally will not sound bad. Compressors and peak limiters can be used to maintain the clipping point constant with variations in level at the microphone but are less effective in raising _intelligbility_ although they may raise average power. So, the ideal microphone for use where there will be noise at the receiving end is one with some rise between about 500hz and about 3000hz. Rise further up will not hurt anything but is beyond the transmitted bandwidth of Drake, Collins, or most other filter type SSB transmitters. Such a response is not as natural sounding as a mic which has relatively flat response in this range.
A final note: Intelligibility in the context being used here referrs to tests of the ability of a listener to recognize words or sometimes sylables under controlled conditions. This is directly related to the success of a speech communication system. There is copious literature on speech intelligibility, processing, etc. Good starting sources are:
The Bell System Technical Journal
The Bell Laboratories Record
The Journal of the Acoustical Society of America
and a number of journals dedicated to speech and hearing research.

Daniel makes an interesting declaration that may be on the mark with the rigs that he has and can listen to side by side. That being said, I find that on SSB and also AM the R-4C with its variable band width provides more listening pleasure and also reduces interference. Even in CW mode, the band width makes for clearer sounding signals. Filterwise, except for the narrower 250Hz in the R4-C, there does not seem to be any difference.

Perhaps there isn't any difference in sensitivity between my rigs or, perhaps, I have not done serious weak signal work to really hear the difference.

perhaps I should have elaborated. in comparison, I do think my TR4C is slightly more sensitive on most bands. that of course, is not an indictment against the R4C, and could easily be the product of a bad tube or misalignment. I am in the process of aligning each and will gladly report my findings when the playing field is level. the TR4C, even on 20-meters has excellent sensitivity and audio. indeed, I can safely state that the audio on the TR4C is far superior to the poorly-designed output stage on the R4C. I also notice distortion products in the product detector that exceed that of the TR4C.

the TR4C is, however, sub-par on AM and CW, and to my mind, really just a very good SSB transceiver. I bought the R4C after being dissatisfied with my new R4B audio. I remember taking the R4B into the lab to better design a product dectector but ultimately lost interest and purchased the R4C with all filters and noise blanker in 1978.

electrically, my Icom 7000 and 7600 outperforms them all. the point however, is that operating these older Drake components is fun. there is something about the experience that brings great pleasure and brings forth so many memories of cold nights, glowing tubes, and spinning the dial looking for weak CW signals on 40 meters at two in the morning.

An old-timer trick for the D-104 without amp is to place a 470K or higher resistor in series with the mic element to mellow out the sound a little more. The D-104 element likes to see a very high impedance load, and it has enough output to drive most rigs with the additional resistance. Too low of a load impedance is what produces the "tinny" sound that some complain of. Info can be Googled.

Noise has a strong influence on articulation and the effect of bandwidth. Under quiet conditions unfiltered, wide frequency range, speech has the best articulation; under noisy conditions speech wich is band limited and which is filtered to accentuate the range of frequencies which carry intelligence (1000khz to 3000khz) will be much more understandable than wide-range speech. So, for best articulation under noisy conditions its best to shape the speech spectrum to accentuate the mid-highs and attenuate low frequencies. Since the power in speech is mostly concentrated in the lower frequencies attenuating them with regard to the higher ones also has the effect of increasing available power for the intelligibilty range.
Microphones meant for high intelligibility under noisy conditions usually have some sort of frequency discrimination as noted above. Typically, "communication" microphones have limited low and very high frequencies and are built so that they have a rising responce curve between about 500 hz and about 300 hz often with a peak at about 2500 hz. Where the transmission system has no other filtering this can make a substantial difference in the understandability of the speech in noise. Where there is some discrimination already in the system such additional filtering must be used with some care. Typically, in transmitters such as the Drake line, only bandwidth filtering is used. There is some discrimination in the audio amplifier, mainly to attenuate the low end before filtering. Usually, this will help reduce intermodulation distortion but is not enoug to cause problems if a rising responce mic is used.
In fact, the difference in received quality due to microphone characteristics will be less than might be expected from listening to the microphone on a flat

amplifier. However, the rising characteristic within the transmitted pass-band will still help to concentrate transmitted energy in the intelligence range especially in the presense of noise.
Amplitude processing:
Many transmitters have some sort of amplitude processing; either compressors, peak limiters, or peak clippers. All of these are for increasing the level of the average power level in speech in comparison to the peak level. Most transmission systems are peak limited, even digital ones. Because, in normal speech, the ratio of peak to average is very high the power available to carry intelligence is quite limited unless the speech waveform is modified so that the ratio is increased. Probably the most effective means of processing for the purpose of increasing the intelligibility in the presense of noise is peak clipping. This must be done with the aid of spectrum shaping. The simplest method is to put the speech through a differentiator, clip it, and then put it through an integrator. While the terms differentiator and integrator suggest something elaborate they are in fact only simple 6db/octave RC or LC filters, high pass before clipping and low pass after clipping. In research done in the late 1940's J.C. Licklidder found that _infinite_ clipping could be used without destroying the intelligibility of speech, provided that the speech was processed as above. Under noisy conditions the clipped speech had better intelligibility than unprocessed speech but not under quiet conditions although the loss of intelligibility there was not severe. For typical ham transmitting conditions about 6db of clipping is sufficient and generally will not sound bad. Compressors and peak limiters can be used to maintain the clipping point constant with variations in level at the microphone but are less effective in raising _intelligbility_ although they may raise average power.
So, the ideal microphone for use where there will be noise at the receiving end is one with some rise between about 500hz and about 3000hz. Rise further up will not hurt anything but is beyond the transmitted bandwidth of Drake, Collins, or most other filter type SSB transmitters. Such a response is not as natural sounding as a mic which has relatively flat response in this range.
A final note: Intelligibility in the context being used here referrs to tests of the ability of a listener to recognize words or sometimes sylables under controlled conditions. This is directly related to the success of a speech communication system. There is copious literature on speech intelligibility, processing, etc. Good starting sources are:
The Bell System Technical Journal

The Bell Laboratories Record
The Journal of the Acoustical Society of America
and a number of journals dedicated to speech and hearing
research.

Have you looked at the Sherwood mods for the R-4C? This is all stuff you can build yourself.

Astatic designed the D-104 to have a rising frequency response. I've never seen a chart of it so I don't know exactly what it does. For a time, when the D-104 was relatively new, Astatic offered a flat responce model as well as the rising responce model but it would seem most sales were of the latter.
Crystal mic impedance looks like a capacitance so its sensive to load resistance. It becomes a series RC circuit and the lower the load resistance the more the low end tends to roll off. By putting a fairly high value resistor in series with the mic the low end is brought up at the price of somewhat lower overall level. Since the output of the D-104 is _very_ high it can stand the modest loss of level.
The response of a crystal mic depends partly on the value of the crystal as a capacitor, partly on the mechanical circuit, that is the diaphragm and its coupling to the crystal. This can be made resonant at some point to raise the response where the designer wants it. Also, there is the

acoustical response effect due to diffraction around the case. The D-104 has a relatively large case so it has a diffraction rise beginning at a fairly low frequency, probably around 2k. This will also make it somewhat directional at higher frequencies. Both of these characteristics are desirable for its usual application.
BTW, the D-104 appears to have been the first crystal microphone on the market, c. 1934. The early ones were mounted in a ring mount with springs a'la the common carbon microphones of the time. The very high output of crystal microphones and phonograph pickups is one reason they became so popular: they did not need much amplification and amplifiers were expensive then. This is also the reason carbon microphones were so widely used and were standard in the telephone industry until pretty recently. Actually a carbon microphone _is_ an amplifier, modulating an external power source to produce an output.
These days, with the low cost of amplfication and ease of providing for extremely high load impedances, electret microphones have replaced all other types in nearly all low cost applications. An electret is a sort of permanently charged condenser mic, the equivalent in a capacitor of a permanent magnet, and, because of their mechanical simplicity can have very good audio characteristics. Because they depend on an extenal amplifier they do require some power but very little, less than a carbon microphone would need for the same output level.
My impression of Astatic over the years is that they made high quality products.

It appears that Astatic changed something in the design
of their crystal mics sometime between about 1947 and about
1953. A 1947 catalogue sheet describes the D-104 as having a
"spring mounted Graphoil crystal element" while the later
catalogue says it is a "Metalseal" element. The same
Metalseal element is used in some other Astatic mics of the
latter date. Crystal elements are vulnerable to moisture so
are sealed in various ways to protect them. Most of
Astatic's elements are based on patents issued to the Brush
Development Company, which itself made crystal mics and
headphones. I don't know if either Graphoil or Metalseal are
Brush or Astatic patents, both companies held several. Its
also possible that it was just a change in name but I rather
think it was an actual change in design.

From: mike
Topic: 3948 Message: 3948

I wanted to replace the faded blue filters on my R-4B, & found a UK supplier of the proper filter material, but the minimum quantity was 1m - enough for many dozens of sets.

Unfortunately I only have the one, so if anybody else would like to renew their filters all you have to do is send me a stamped, addressed envelope, preferably with a piece of card inside, to prevent creasing.

This is UK only, I'm afraid. If the envelope doesn't have UK stamps on it then our dear PO won't accept it.

Email me & I'll email back my address.

I don't think so, Joe. The only element I remember seeing from Heil for the d-104 was an electret element for the Icom rigs to cater to their mic designs that require a separate power source. The amplified d-104s have become popular for that purpose.

By several counts there are other elements out there that do the job much cheaper and just as well, or better.

It would be interesting to know how many NOS D-104 elements work. Rochelle salt crystal elements are sensitive to both humidity and high temperatures. Commercial units were sealed in various ways to prevent moisture from affecting them. The salt is delequescent, meaning that it will absorb moisture and go into solution. Also, it becomes less active as the temperature goes up being nearly inactive at about 100F and will be permenantly damaged at about 113F. These are temperatures which are common in some areas (I think the East coast is getting them now). Its pretty common for crystal microphones, headphones, phono pickups, etc, to be inactive due to leaks in the sealing or to exposure to high temperatures. That applies to a packaged replacement part so that the chance of such a part working will depend on how well the package is sealed and its history.
Crystal elements were replaced with piezeoelectric ceramics beginning in the late 1940s, the D-104 was available with either. The ceramics are much less vulnerable to moisture and temperature but have a much lower output level. One feature of the D-104 was its very high output level, rated in the old literature as 45db below one volt per bar (by bar is meant micro-bar). The ceramic version, the D-104C, was rated some ten db below this. However, its much more likely that a ceramic mic will still be working.

Daniel -

Yes, 100W output on 75M is low. 130 to 150 is more typical with finals
in good condition.

When the relay drops out, whether SSB VOX or CW semi-breakin operation,
the Final BIAS current will show on the meter. It should be 70 mA. If
it is reading 100 mA, the BIAS needs to be readjusted to return it to
70. Excessive BIAS current will lead to final tube degradation and
reduced output, so may account for your reading.

From: arsnf7z
Topic: 3957 Message: 3960

Gary,

the current I show is about ~100ma when not keying, but the VOX relay has NOT dropped out yet. is that what you are saying? I'll check, but I do think it was higher than the BIAS point I set. not by much though, if at all. yes, I typically set it at 70ma and have to reset it after using the AC-4 with the TR4C.

the odd thing, is that I hear a ~650hz tone in the R4C (sidetone off) when I use the T4XC in 'rcv' and 'xmit' tuning mode. it only occurs when I have the INJ cable attached ... and it exists on all bands, off frequency. I don't have my schematics, but it almost appears to be an audio loop and not RF. this tone, exists at a lower amplitude until the VOX relay finally drops.

thanks for your assistance. I am up in Canada, on our sailboat, playing with Drake radios during the heat of the day!

NF7Z

Daniel -

Yes, I mis-spoke in my first message. The BIAS will show UNTIL the relay drops out, at which time the PLATE meter should read zero.

The TR-4C should be 100 mA BIAS current.

I'm not sure about the tone. You may be hearing the Carrier Oscillator that is offset about 800 Hz in CW. If the SIDETONE is present (at reduced volume) when the key is UP, then the C107 electrolytic is probably dried out.

Hi jb,
I used the D-104 with the C line until the third baby came along and sold it. (I could get more for the FS-4 today than I got for the whole setup!)
Today I use it with a TR-3/RV-3 with no complaints. Most people can't tell the difference between it and the Shure 444D.
I am sure that the responce curves are different, but these are communication mics, and I can't sing anyway!
Any NOS stock is by definition old, mine just happens to be in good shape. I guess it just depends on the environment it has been in.
The D-104 just happens to be the first mic I saw in the '50's when I got interested in ham radio.

Mike, please let us know how you like it. I have seen NOS elements for the d-104 on e-bay from time to time. Since your original still works it would be interesting to compare the two.

God bless

Actually the response curves for the two are very similar. Both have a rising curve from about 1khz to about 3khz where it peaks about 12db above the 1khz level, then it rolls off very steeply. On the low end the 444 is fairly flat from 1khz to about 300hz and then rolls off very quickly the D-104 slopes off more gradually below 1 khz and does not cut off sharply although it has very low response below about 200 hz. I am not surprized that they sound pretty much alike.

3965. TR4C filter cap; shame on Drake

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-07-12 14:49:14 UTC
From: Dick KF4NS
Topic: 3965 Message: 3965

Ok guys, I made my decision to just go ahead and replace the can with 4 individual caps.

Just for the heck of it, I cleared the way underneath and lifted the unsoldered tabs along the chassis edge with a screwdriver. I then decided to try a wiggle of the can to see if it may be possible to just rock it until the two soldered tabs break.

WHOA! What a shock! (not literally) The can just lifted out. What had appeared to be huge globs of solder on the other two tabs was just that. This rig was never worked on before so some tech in 1974 failed to check his work, probably on a Monday.

Sure simplified my work though. Now all I have to do is solder my new caps to the wires and heat shrink them. I still may gut the can and put the new caps in there just for looks.

Be interesting to know if the old cap is still good and
was just not grounded. Its possible that the tabs made a
good enough connection for a time but not after some
corrosion got started.
BTW, I found a never soldered connection in my R4B,
don't remember what it was.

Dick,

Unsoldered connections, on wires or tabs, have been noted in
isolated cases in Drake gear. However, due to wire wrap and
crimp, many of these connections have enabled perfect
performance even after 30 or more years of being like that.
So what you are seeing is likely the exception rather than
the rule.

73,

Evan, K9SQG

In my reply to this message in the "other" Drake list I
mentioned having found an unsoldered connection in my R4B. I
don't remember where it was but the radio worked.
I was taught long ago to wire so that the solder was
not relied on to make the connection. However its often not
possible to make proper wrapped connections when making
repairs. I suspect in this case the tabs were making good
enough contact for the filter caps to work until the
connection surfaces got a bit corroded. Perhaps the original
soldering iron did not have enough mass; this is essentially
sweat soldering and the chassis will dissipate the heat
quickly if the iron is not massive enough. Mass is more
important than temperature for this. A hot but small iron
will be cooled so quickly it will have the described result:
a blob of solder on the connection but no actual solder
joint.

3968. TR-4C crystal filter specs?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-07-12 18:15:44 UTC
From: w1kilofoxtrot
Topic: 3968 Message: 3968

I've finally gotten a TR-4C (to replace the TR-3's I had)!

The first thing I had to do was fix a low audio problem advertised when I bought it. The RF gain was counter-clockwise. First problem solved!

The Upper Sideband crystal filter may be shot, since I can't make the 'noise' even between upper and lower. I'd like to test it on my Network Analyzer, but I need to know the filter impedance. I'm guessing it's around 500 ohms, but it would help if some one (Garey?) might know off the top of their head. I didn't find anything in the archives.

And, I think I'd like to populate the 10M crystals, so I need 42.5 and a 43.6 MHz crystals...

Steve -

There seems to be some some confusion over the impedance of the TR-4 filters. Some say 500 ohms, others say 1000 ohms. The R-4C and 7 Line filters are easy, they're 50 ohms.

I've never actually swept one, but I'm sticking with 1000 ohms until someone convinces me otherwise! :-) Part of the confusion may be that the earlier "soupcan" filter was I believe, 500 ohms.

Let us know what your measurements show!!

Interesting Mike, thanks.
I know some like to use different mics between rag chewing and busting thru on DX and contests; the d-104 seems to lean towards the busting thru mode. Was wondering how a different element might change that.

Richard just responded also, stating that there wasn't much difference at all. Good to know.

I have a few mics but only the 444 is wired up yet. Seems to do pretty well with my voice, which I would catagorize as mid range on tone and a bit soft on volume. It get higher and softer when during allergy season. =) Need to play a bit more with these.

God bless

Hi Richard,
Thanks.

Wow! Salt? I would never have thought. No wonder there are replacement elements still out there. They must have made a ton of them, knowing ahead of time how perishable they might be.

Was that common with other crystal elements, other brands? I always imagined someone polishing down all these little quartz crystals like they would in a watch. ...something certainly more substancial than salt.

I got to say, I have gotten quite an education from you, especially in this thread. I had been gleaning info here and there but you really tied things together and explained a lot. Thank you. You must have been a teacher....should have been anyways. Your efforts and experience are greatly appreciated by this thick head. =)

God bless

Meant to ask but forgot to add: Do you think most of those NOS elements for the d-104 are the ceramic? Were the salt ones sealed that well?

thanks

3973. Re: [DrakeRadio] TR-4C crystal filter specs?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-07-12 20:00:12 UTC
From: William Houghton
Topic: 3968 Message: 3973

Steve,

This seems to be a common problem, the audio noise level being significantly different between the "X" and non-x position of the sideband switch making it close to impossible, in my opinion, to get the noise pitch to be close to equal between the two sidebands when you try to adjust the 9MHz osc. I had this same problem with my TR-4C and solved it by using DeOxit on the sideband switch. It took about three applications over a few weeks time before it stayed fixed. In my case this also affected the RF drive in SSB observed with a single tone test as well as the received audio.

Bill

Subject: [DrakeRadio] TR-4C crystal filter specs?

I've finally gotten a TR-4C (to replace the TR-3's I had)!

The first thing I had to do was fix a low audio problem advertised when I bought it. The RF gain was counter-clockwise. First problem solved!

The Upper Sideband crystal filter may be shot, since I can't make the 'noise' even between upper and lower. I'd like to test it on my Network Analyzer, but I need to know the filter impedance. I'm guessing it's around 500 ohms, but it would help if some one (Garey?) might know off the top of their head. I didn't find anything in the archives.

And, I think I'd like to populate the 10M crystals, so I need 42.5 and a 43.6 MHz crystals...

73,
Steve

Its A salt, posassium sodium bitartrate. Crystals can be made from a mixture of sodium carbonate (washing soda) and sodium tartarate (cream of tartar), there are instructions on the web. The material is delequescent, that is, the crystals will absorb moisture from the air and go back into solution. When used in crystal microphones, phono pickups, headphones, and crystal disc cutters, the crystals were used in combinations that increased their mechanical motion. These were of two forms called "benders" and twisters" depending on how they were fastened togeter.
Rochelle salt is very active meaning that the amount of motion produced by a voltage is comparitively great, or that the voltage produced by stressing the crystal is great. The problem is that the crystals are destroyed by being exposed to moisture or to temperatures over about 113F. In order to protect them from moisture the active elements were sealed in various ways. Usually both sides of the crystal were covered with metal foil cemented in place with something the crystal would not absorb. One patent used gelatin. The elements in a couple of Brush headphones I dissected were in what appear to be rubber sleeves but might be plastic. Evidently, the seals were sometimes a bit leaky so that the element would eventually disintegrate when exposed to moisture but the crystals are also vulnerable to high temperatures and to fracturing either from being driven by too high a voltage in the case of headphones or cutters, or by mechanical damage in the case of a phonograph pickup or in any of them by physical impact like being dropped hard. Ceramic materials are much less senstive to moisture and heat but are still sealed. Their main drawback is much lower output but they began to replace crystal pickups and

microphones in the 1950s because they were so much more rugged and because amplification had become cheaper so that the extremely high output of Rochelle salt crystals was less necessary. Crystal phono pickups are also not well suited to microgroove records because they tend to be too stiff making higher tracking pressures necessary with the attendant rapid wear of the record.
I have no idea how well D-104 elements are sealed but, since heat and mechanical shock are still problems even with a perfect moisture seal, its hard to know how many of them are still good. Also, it appears from their advertising that Astatic may have changed the method of constructing the elements at some point around the late 1940's. The earlier ads refer to "Grafoil" and later ones to "Metalseal", perhaps the same thing with a different name but the later one may be different and more effective.

OOoops, mis-spelled tartrate a couple of times. Also,
the components needed to make Rochelle salt crystals are
sodium carbonate and _potassium_ bitartrate. The latter is
known as Cream of Tartar, it is also the stuff called
"beeswing" sometimes found in wine.
Crystals are not too hard to grow but I don't know if
they are practical for making microphones.
BTW, Brush crystal headphones were long sold as
high-fidelity phones plus they have a very high impedance
(more than 100K) making them useful for audio bridge
measurements and crystal set radios. I took a couple apart
to see if they were fixable. They aren't. They appear to be
completely assembled by cementing, crystal element cemented
to pads in the case, diaphragm cemented to the case at the
edges and fixed to the actuating rod with what appears to be
bee's wax, and finally the caps cemented to the cases. I
have about eight capsules, ONE of which still works.

I've not swept them yet, but someone offered that the terminating resistors hold a clue. The schematic, and radio, have 470 Ohm terminators, so I'm assuming the filters are 500 Ohms, plus or minus.

A previous owner thoughtfully drenched all the switches in some sort of 'cleaner' which converted all the silver surfaces to silver sulfide, conductive, but ugly black. A little light wiping seems to be getting it off...

Little by little...

My TR-3s were never 'equal' from upper to lower, but they were fairly close. This one is -way- off. I'll continue testing, and let you all know what I find!

OK, Richard. Now I am suspecting that you're pulling my leg. =)

Very interesting. One of the reasons I got into boatanchors and related
items is a fascination for how things evolved.....and an incurable
desire to take things apart tho see how they tick.

Which brings up another question: I had picked up an old Shure 51 and
the element was in pieces.....no, it was that way before I took it
apart. =) From what I can tell, it appears to be a magnetic element.
Haven't had any luck finding a replacement. What would you suggest?
Can these still be found? Cosmetically this is in real nice shape,
screen and label as well. Would really like to be able to use it with
a Drake or maybe my Kenwood 250.

thanks

God bless

Steve et al,
FWIW, I found that the easiest way to set the USB/LSB balance, if you dare call it that, is to tune in a 40M broadcast station with the mode switch set to SSB and adjust C130 for the best balance while switching the sideband switch back and forth. If the filters are a bit off, setting C130 with a freq counter is of little use.
Good luck and 73, Dick KF4NS

> leg. =)
>
Nope! See http://www.seawhy.com/xlroch.html for a
method. This one starts with bicarbonate of soda and makes
sodium carbonate from it by baking it. In many places one
can obtain pretty chemically pure sodium carbonate AKA
washing soda or soda ash (for the anhydrous form). It is a
common photographic chemical but was long avaiable in
grocery stores. I have not seen it there for some time but I
think some hardware stores still have it. Also possibly
swimming pool supply places. Cream of Tartar is, I am pretty
sure, still available at grocery stores.
I don't know what quality of crystal one gets but
likely it will be good enough to demonstrate
piezoelectricity. Actual crystal microphones, headphones,
phono pickups, were made of multiple crystals cemented
together so as to magnify either their output or their
mechanical motion when excited by an electrical current.
If you can wade your way through the "patentese" there
is something to be learned from the patents held by the
Brush Development Company. One of these, issued to Charles
B. Sawyer, is one of the earliest to describe practical
piezoelectric devices USP RE20213 Its probably the first
description of a "bimorph" or bender type crystal element.
Most of the early patents on piezoelectric appliances were
owned by Brush. A Google Patents search for "Brush

development company" with the quotation marks will find them. Many of the earliest ones were issued to C.B.Sawyer and A.L.W. Williams. Astatic, and all other makers of crystal microphones, phono pickups, and other devices (like stress detectors) were licensed by Brush.
Among the Brush patents are some relating to the growing of Rochelle salt crystals in production settings. Electrodes can be made from ordinary aluminum foil. I am not sure what sort of cement should be used, something that does not contain water, probaby airplane glue would work. Whatever is used must not dissolve the crystals.

<Cream of Tartar is, I am pretty sure, still available at grocery stores.>
Oh, yeah! In the spice rack along with the Arm & Hammer bicarbonate of soda. That's what makes it so facinating. Have no idea what you would use it for but I did recognize it.

I tried to tell a couple of the guys at work (civil engineers who would usually be into techno-peculiarities) and couldn't covince them, that is the ones that didn't respond with, "Cream of what?". Of course they have other reasons to know me too well to bite too quickly. =) Now I know how the kid who cried "wolf!" felt.

Really, fascinating stuff.
Thanks Richard.

God bless

Cream of Tartar is used in cooking and in baking as an
emulsifier. I thought it was an ingredient of double-acting
baking powder but I found the ingredients list for Clabber
Girl Baking Powder and it has something else in it (sodium
aluminum phosphate). BTW, I have never been able to find a
definition of what a clabber girl was or what clabbering is.
The imagination runs wild.
Anyway, this is getting pretty far afield for a Drake
radio list.

3995. Sidetone sounding strange today: ringing & clicking

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-07-18 23:18:33 UTC
From: billykatzz
Topic: 3995 Message: 3995

Maybe it's my OCD kicking in, maybe it's this crazy heatwave with 3-digit temps, but I can swear today that when I fired up my TR-4Cw, the sidetone, particularly when wearing headphones, had a new sound: sometimes a clicking, sometimes a faint ringing reverb quality that I hadn't noticed previously. In addition, the Load control seems kind of unresponsive when I'm trying to tune up.

Is this a case of my 6JB6's preparing to go South on me?

Tighten all circuit card mounting/grounding screws. Use a tiny drop of
DeOxit on the band switch rotor tabs. DeOxit clean tube pins. Should
cure the wandering electrons.

3997. Using FS4 with SPR4

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-07-20 12:02:25 UTC
From: TERRY/N4SuB
Topic: 3997 Message: 3997

Hello to all-I would like to hear from anyone who has used the Drake FS4 with the SPR4 receiver. I am fortunate to have both and believe this is a perfect match. The manual for both is VERY vague on the hookup. How does the range selector come into effect? ANY info would be greatly appreciated.
73 & tnx--Terry N4SuB

Topic: 3997 Message: 3998

Terry -

The first thing is you need a 9.59 MHz crystal in the FS-4. The 9.6 MHz crystal was standard for the R-4(any) series.

Since the accessory crystals are inside the SPR-4 rather than on the back panel as in the R-4(any), you have to route the INJ cable from the FS-4 through a hole in the back of the SPR-4. The receiver end of the INJ cable should have the shield connected to the chassis, and the center conductor connected to the single pin of one of the accessory crystal sockets. The pin you want is one that is connected to the PC trace that goes around the outside of the board, connecting all the crystals together.

If you don't have the original INJ cable supplied with the FS-4, keep the cable as short as possible. Any coax will work, but the lower the capacity, the better.

The RANGE selector must be set to the appropriate range for the frequency you are listening to. The PRESELECTOR must also be peaked for the correct frequency.

3999. SP75 -- power problem

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-07-23 20:24:32 UTC
From: Brenton Crowhurst
Topic: 3999 Message: 3999

Greetings to the list again --

While I've had some complimentary reports on my TR7 audio with just my microphone, when I kick in the SP75, there was a complaint of either rf getting into it, or a 60hz hum.

I listened to myself with headphones on my short waver receiver, and there is a racket.

Here's the set up. The SP75 is powered from the aux power on the back of my ALS 600 linear.

I know the sp75 manual says use the tranceiver's power supply outlet, but mine's dead.

Do I need to fix the Drake PS?
Can I power the SP75 another way?
Do I need ferrite somewhere? Everywhere?

Other possibly pertinent info:

Antenna's a Butternut vertical, ground mounted 40 or 50 feet away, with two "ugly baluns" in line.

No TVI. The only other indication of rf in the house is the powered computer speakers in the next room.

Thanks in advance for suggestions.

Brenton

Brenton -

Sounds like ground loops and/or RF getting into the SP-75. The main problem is that the SP-75 is getting it's power from a device plugged into the line and probably grounded through the power cord and/or the antenna coax, and the coax to the TR-7, and ... Ground loops!!

There is a 1A fuse on the AUX DC jack on the back of the PS-7. This is often blown by someone plugging in either a device drawing considerably more than 1 Amp, or for some unknown reason plugging in a shorting plug (I found one of those once).

If it was mine, I'd replace the fuse, then plug the SP-75 in there to see what happens! I've never had an SP-75, but I would hope that the power lead is shielded cable terminated in an RCA Phono jack.

There is RF filtering and reverse polarity protection just inside the SP-75, so shielded cable to the TR-7 should be sufficient. You do NOT want ANY other grounds to the SP-75 chassis or to the microphone plugged into the SP-75. The power lead should be the ONLY connection between the SP-75 and any other gear in the shack.

If proper grounding doesn't solve the problem completely, (although it should get rid of any 60 Hz hum,) a snap-on ferrite on the AUDIO output line might grab RF.

Garey,

I checked the fuse, and it's good!

But I take your point about ground loops. It's gotta be run from the Drake supply or else, maybe, batteries.

Brenton -

You DID check the fuse INSIDE the power supply, NOT the one on the back panel?

That supply comes through the INTERNAL fuse directly from the main output of the supply.

Hi Brent,

I ran mine from the same generic 12V power supply that I used to runthe TR-7 from, before I got a PS-7, with no issues. But it was essentially connected tht same way as it would be with the PS-7. The RF feedback problem I was having at Field Day turned out to be an unconnected shield in the headset cord. I had added a heavy braided ground strap between the case of the SP-75 and the gound lug on the back of the TR-7 while troubleshooting the headset at the recommendation of someone on this list, I left it in place as it seemed to be causing no harm.

Powering it from the amplifier may just be bad karma. A little bit if RF there may just be enough to cause your problem. Make sure your mic cord is good, and the shield is connected at both ends. As Garey said, look for ground loops. It is possible that it may only be happy if run from the same PS as the TR-7.

Jim,

Thanks. I hope you guys on this forum know what a resource you are to techno-tards like me -- to use a politically (?)correct term!

Finding the the PS 7 aux 13.? volt outlet was dead, I winged it, recognizing the SP-75 manual probably knew better. I better fix the source, knowing now the outcome was pre-ordained.

It tickles me that this "ancient" rig sounds so good, without amp or SP-75. I'd like to havez the same results with the SP-75 on duty!

I'll double check the mic grounding.

Also, we have a ham, at work, in the electrical engineering dept. He spotted my Butternut hf9v in the trunk at 50 paces, when I had the back open, and came over to introduce himself. Such resources are not to be ignored! Bet he'd have a look see if I told him it was "hosital related equipment"!

Heheh.

Huh? Wha?

Uh oh.... No, I checked the fuse accessible from the back panel.

ok, now where did I put that screw driver... I'm sure I'd reconize it if'n I saw it. ...

Brenton -

You DID check the fuse INSIDE the power supply, NOT the one on the back
panel?

That supply comes through the INTERNAL fuse directly from the main
output of the supply.

4008. RE: [DrakeRadio] SP75 -- power problem

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-07-24 14:17:21 UTC
From: Brenton Crowhurst
Topic: 3999 Message: 4008

Alright, now I think we're in business. With the top of the PS taken off, I easily traced a wire back from the Aux output jack to a circuit board at the front, left side of the thing. A blown fuse on that board reads, if my strained eyes have it right, 1A 250 V.

I believe this is where you were directing me, and suspect this is my culprit!

Yup! Figured out that screwdriver thingy, didja?

That's an "MDL" fuse, meaning that it is a "slow-blow" style. Probably
not going to find it locally, unless Radio Shack has one. If not, a 1A
fast blow (standard '3AG') will work for now, as I think the SP-75 only
draws about a tenth of an amp.

Garey

4010. RE: [DrakeRadio] SP75 -- power problem

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-07-24 15:12:46 UTC
From: Brenton Crowhurst
Topic: 3999 Message: 4010

Hah! That explains the "3AG" that also appears on the thing, but I'm really straining "me glazzies" now.

Thanks Garey, I'll see if I can't get this back on the air today, and find out how this rig sounds when the compressor doesn't have ground loops to work against, not to mention noise from the linear to compress along with my voice!

Yup! Figured out that screwdriver thingy, didja?

That's an "MDL" fuse, meaning that it is a "slow-blow" style. Probably
not going to find it locally, unless Radio Shack has one. If not, a 1A
fast blow (standard '3AG') will work for now, as I think the SP-75 only
draws about a tenth of an amp.

Garey

Brenton Crowhurst wrote:
> Alright, now I think we're in business. With the top of the PS taken off, I easily traced a wire back from the Aux output jack to a circuit board at the front, left side of the thing. A blown fuse on that board reads, if my strained eyes have it right, 1A 250 V.

4011. Re: [DrakeRadio] SP75 -- power problem

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-07-24 15:54:41 UTC
From: Garey Barrell
Topic: 3999 Message: 4011

Yep, sounds like the guy who blew that fuse couldn't find an "MDL"
either! :-)

I've forgotten all the percentages and times, but the "MDL" just means
that the fuse will take a short duration overload to allow for turn-on
surge currents, while the "3AG" pops pretty quickly.

Probably not significant for use with the SP-75 since it doesn't have
any big caps on the input. As I recall it has it's own 1/4 A "3AG" fuse
internally for the reverse polarity diode protection.

For a fuse in a 12 volt circuit, I would suggest visiting an auto parts store
and purchasing some low-voltage fuses. There are differences, and a 250 volt
fuse can act quite differently in a 12v circuit than a 32 volt fuse.

Thanks Jim,

I replaced it with what was in it, and the PS 7 now runs the SP 75. No idea yet how it sounds.

But I better not rest easy just yet, and take your suggestion of getting some more proper fuses! .

Hopefully it'll sound just fine.

The issue is interrupting capability of the fuse.

Bigger problem if you try to use a 12 V fuse on a 250 or 120 volt AC circuit.

Jim / Brenton -

Not really. The difference between 32 and 125V fuses is in their ability to 'clear' the higher voltage. You should NOT use a 32V fuse on 125, but no reason not to go the other way.

Typically you don't see 32V fuses in less than 8-10A sizes, usually for automotive use. My MG had TWO 30 Amp fuses, period! :-)

The MDL will withstand 200% of rated current for 5 -10 seconds, and 135% for an hour.

The 3AG will withstand 200% of rated current for 2 minutes, and 135% for an hour.

It also depends on the quality of the fuses. Reputable manufacturers come
pretty close to the curves, but I've heard horror stories about cheap no-name
import fuses that don't even come close to opening when they should.

Remember, the transistor will always blow to protect the fuse...

Funny, I haven't heard that one in a while (except when I say it). I sometimes have to explain it to the younger techs.

I just explain that the same magic blue smoke is inside old Chevy engines, with
the same effect. When all the blue smoke has left, it doesn't work anymore.

There is blue smoke inside of Chevy engines and electrical parts. When you let the blue smoke out of the parts, they don't work anymore. Therefore, the magic blue smoke is what makes the parts work. Chevy engines are slightly different, as they will begin to leak the magic blue smoke as they age. But they have plenty inside, as they are big and heavy. As long as some is left inside, the engine will run. When it runs out of magic blue smoke (can no longer emit any), it stops running.

For all the whipper-snappers - in the era of $100 used cars (1960, thereabouts) the 49-51 Chevys were famous for wearing out their rings and sending blue oil smoke out the exhaust. On the plus side, they seemed to last forever, as long as you put in a quart of oil or so each week. (In those days, Oil was only 19-29 cents a qt, as I remember...)

4034. comparing Drake equipment to Collins ...

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-07-31 17:24:57 UTC
From: arsnf7z
Topic: 4034 Message: 4034

I keep reading something that goes like "collectors buy Collins, but real users buy Drake". in the 70's, it seemed only the very rich owned Collins and as a student, I finally found the coins to buy a Drake R4C. the matching T4XC and L4B were not in my reality. I must say that I've never ever sat down and spent time with a 75S3 or KWM2, and so I am left wondering how they actually compare to the Drake experience.

it seems to me there is no comparision mechanically. I don't harbour complaints against my Drake equipment, but there is something special about how well the Collins gear was built. and yes, I realize you paid for it! how about electrically and operationally? any major differences surface between the two? I enjoy the passband-tuning, but I have never thought much of Drake audio on R4B/R4C receivers, though I do think the TR4 audio is nice.

just curious ... my reflections were that Quement Radio in San Jose, probably sold dozens of Drakes for every Collins that went out the store. I seem to recall most hams thought the Drake was a better deal.

thoughts?

I have both as many of my friends. We all agree Collins has it hands down on the mechanical side of the equation. Mechanically, Collins is a thing of beauty. However, we all feel Drake has better electronic circuits. This is not to say collins has bad electronics. Also, the PTO in Drake tunes 500 khz which is more then Collins so you don't need as many crystals. The AGC circuit in Drake is by far better then in Collins. 6146 tubes used in Collins will give slightly better distortion figures then 6JB6 tubes used in Drake, but does it really matter? 6146 tubes cost less then sweep tubes and easier to find today. Drake gear is a marvel in what you can do with inexpensive parts and still retain reliability. I love them both. In today's used market, Collins has better collector value then Drake but Drake is a much better deal if you want a really good radio for a great price. I would not go near any Drake gear cobled up with Sherwood mods and neither would a couple of my close knowledgeable friends.

Lee, w0vt

I keep reading something that goes like "collectors buy Collins, but real users buy Drake". in the 70's, it seemed only the very rich owned Collins and as a student, I finally found the coins to buy a Drake R4C. the matching T4XC and L4B were not in my reality. I must say that I've never ever sat down and spent time with a 75S3 or KWM2, and so I am left wondering how they actually compare to the Drake experience.

it seems to me there is no comparision mechanically. I don't harbour complaints against my Drake equipment, but there is something special about how well the Collins gear was built. and yes, I realize you paid for it! how about electrically and operationally? any major differences surface between the two? I enjoy the passband-tuning, but I have never thought much of Drake audio on R4B/R4C receivers, though I do think the TR4 audio is nice.

just curious ... my reflections were that Quement Radio in San Jose, probably sold dozens of Drakes for every Collins that went out the store. I seem to recall most hams thought the Drake was a better deal.

thoughts?

Daniel,

I have owned both C-Lines and S-Lines (still own my S-Line gear). For the money, the R4C and other Drake receivers are impossible to beat and several ways, IMHO, they out perform the 75S3C (especially the AGC). But, like any radios, the Collins shine as well, albiet differently. Both radios, when properly aligned, are wonderful to operate and perform very nicely.

But you hit the nail on the head when you bring up the mechanical construction and "feel" of the Collins. That is hard to beat in any radio including todays radios. My Collins gear will go to grave with me.

Happy Trails

Daniel -

Others have hit it on the head. The _mechanics_ of the Collins are things of beauty. However, that level of mechanical design is expensive, and in reality does _nothing_ for your ability to pull a signal out of the aether! The Collins circuitry is also elegant, and, operating on a lower B+, has less internally generated noise. This also is nice, but give you no real advantage in 'on the air' operation since the HF bands are limited by _external_ atmospheric noise, not to mention every other &*&^$% piece of electronic junk (junk defined as anything NOT a radio) in our world.

I have _an_ S-Line, several Drake A, B and C Lines, 7 Lines, and an R-8A. The Drake gear is on three (or four) desks, the S-Line is in the closet in boxes. The one I go to FIRST when I want to get on the air is the B-Line. To me this is the epitome of Drake's 'dynasty', fully refined, and before they went all 'solid state' on us! :-) The audio, AVC and ease of use are just RIGHT. I prefer the gentler slopes of the Passband Tuner over the crystal filters of the 'C', but I have developed an 'internal' filter that allows me to find and listen to one CW signal among several. The C-Line MAY be a little better on SSB because of the filter capabilities as it is more difficult to pull one voice out of several.

So... If you need the feel of a fine watch as you tune around the (restricted, 200 kHz) bands of the Collins, more power to you. If you just want to 'get on the radio' and talk to someone, you won't give up a thing by using Drake.

I remember what happened when Drake came out with their stuff, probably the B line is what I am thinking of. They blew Collins out of the water because they offered comparable performance at about half the price. Collins stuff was built pretty much to JAN standards but Drake equipment has survived all this time and is still being kept and used. I think Art Collins built his business on not compromising quality and was successful selling very up-market, nearly custom, gear to the rich folks during the depths of the depression. He expanded this into military, broadcast, and aviation equipment when these markets would stand the price of deluxe quality. Collins also had innovative engineering such as the famous auto-tuning system, the tunable IF receivers, really a sort of elementary frequency synthesizer, the linear permiability tuned oscillator, and the early adoption of SSB. Drake came along with a different kind of innovation. They found ways of translating the very expensive Collins production methods into much less expensive versions that still had the same level of performance (or sometimes greater). That was a tour de force. Several other manufacturers (Swan for instance) also tried to go head to head with Collins but none seems to have made the place for itself that Drake did.
The history of the companies who supplied communication equipment is interesting because most of the first ones failed after WW-2. They simply did not understand the shifting markets. Hallicrafters did employ some innovative engineering but seems to have just adopted whatever the lastest rage was without sufficient refining and too often had poor mechanical performance. Their object was obviously to provide a lot of features for the price but without enough consideration of actual performance level. Drake was also trying to meet a price window but by offering top quality for a more reasonable price rather than a plethora of features, a very different objective and one which

ultimately proved more successful.

Well, it reached the point for a while where it cost as much to fill the gas tank in my Toyota as it did for a running used car when I first started to drive. Of course, the money was worth ten to twenty times what it is now. By that standard gasoline is no more expensive now than it was in 1960.

This is an interesting analysis by Richard, and others.

I'm curious if I can tempt you to apply this analysis to more modern, state of the art gear?

The reason I ask is that, in coming back into ham radio after 16 years qrt, I was delighted to read on the net that many modern rigs, with all their features, shouldn't make me feel obliged to go and get one -- that something like an old Drake could still hold it's own very well indeed.

Brenton,

I'll probably be lit up for this but, the Elecraft K3 kicks butt on all of these older radios...and, its kinda built to the Drake standards, i.e., not Collins quality but nice and definitely good enough (plus outstanding customer service). Just my humble opinion. That is not to say these older rigs don't perform well because they do and I enjoy the heck out of using them.

Now, I'd better go hide and put on my hard hat :-)...

I don't know much about the current crop of equipment.
The newest thing I have is a Kenwood TS-520S. Its a nice
little tranceiver but limited compared to the Drake B line
twins I have. The receiver has fixed bandwidth, no notch
filter and no passband tuning. There _is_ a narrow band CW
filter avaialable for it but the BFO frequency is fixed. Its
really intended for use on SSB only. Although new by the
measure of other equipment I have its actually pretty old.
What impresses me about modern gear is how much stuff
it does. Because of integrated circuits and microprocessors
modern receivers often have spectrum analyser displays, all
sorts of variable filtering, presets for everything, lots of
nested menues. Same for the transmitters and transceivers. I
hear lots of bad signals on the air because the user can't
resist playing with the equalizer and compressor settings
and really have no idea what they are doing or what their
rigs sound like.
Also, something like a Drake B or C line or even a TR-7
is supportable by the owner, Certainly Collins S line stuff
is. Modern equipment often depends on custom made LSI chips,
available only from the manuacturer and trouble shooting
digital stuff is a bear at best. Some of it works very well
but I wonder how much will still be around in forty or fifty
years, or, perhaps even in fifteen. All feature heavy like
cars are. I really don't need all that stuff.

Maybe I am just a bit of a Ludite. I earn my living
from digital television. Nearly everything in the plant is
now either a computer outright or a computer disguised as
something else. No one needs to know any basic electronics
anymore. Just how to reboot stuff.

I will have to search out Elecraft, you are the second
person who has mentioned it favorably recently (can't
remember the other).

Mike,

I second your comments about the K3. I have serial #2569 and it works great. Now, I still use my B-Line, TR7A and Omni VI+ a lot as well. If I can only get my %@#@$ Galaxy GT-550A running right, I'd be a happy camper...

Brenton,

I'll probably be lit up for this but, the Elecraft K3 kicks butt on all of these older radios...and, its kinda built to the Drake standards, i.e., not Collins quality but nice and definitely good enough (plus outstanding customer service). Just my humble opinion. That is not to say these older rigs don't perform well because they do and I enjoy the heck out of using them.

Now, I'd better go hide and put on my hard hat :-)...

Jim and all,

Radio equipment is like guitars. You're not really a collector until you have more than two of a particular model.

73,
Bob AD3K

I've heard good things about the K3, but I have never had the chance to operate one. I would welcome a modern radio that is as pleasurable to operate as a vintage Drake.

What it's all about for me is the receiver. How does it sound, how does the AGC work on your ears, how easy is it to dig signals out of a crowded band, do the electronics "get in the way" of the signal? How do you feel after several hours of contesting? Leaving a rig with a splitting headache is enough to turn one off to a brand for years. The Japanese seem to have problems getting the ACG right, and the signals sound all squashed up against a glass wall to me (I'm leaving Ten-Tec and Elecraft out of these comments as I have no experience with them). On a decent vintage rig, the band "breathes". There is space between signals. The audio is easy on the ears. Maybe recent offerings have gotten better, I don't know.

This presentation by Rob Sherwood is interesting reading:

http://www.sherweng.com/documents/Dayton2007w.pdf

Some of you have seen this already.... :)

On the transmit side, they also tend to do the ALC wrong in newer rigs, as described here:

http://www.sm5bsz.com/dynrange/alc.htm

Makes me want to run right out and buy one! I remember hearing tales about hams spending literally hours and hours tweaking and tuning to get the best sounding, cleanest possible signal on the air. Now, it seems the tendency is to just buy a box and hook up an antenna.

Bells and whistles are sure cool, but I wonder how much of that stuff most people really use?

So, how does it SOUND?

73

Hi Jim,

Quirky is an understatement hi hi. Just got done recapping the PS, replaced all electrolytics and 1W/2W resistors. Overhauled the AVC board completely. Probably need to do a complete alignment now as it's fine on 40/80M but deaf on 20 on down. Definitely not a Drake hi hi...

Definitely, and radio that old can benefit from a full alignment. I need to get mine back on the bench someday, I seem to have a gain problem somewhere in the IF.

4051. Drake and guitar amps ...

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-01 00:29:38 UTC
From: arsnf7z
Topic: 4034 Message: 4051

there is little argument that modern radios out-perform Drake and Collins in many areas (though my R4C is more sensitive and pleasurable to operate than my Icom). for me, watching the colour analyzer screen gets old rather quickly and one should realize how much you had to pay for that 'feature'. I should say, I am *not* a contester.

I used to own a guitar amplifier company, did guitar amp design, and worked with Carlos Santana to build the 'ultimate amplifier'. well, I have that amplifer sitting at home in a closet. Carlos is a spiritual guy and his guru told him to simplify. to get back to the essence of 'tone'. and so, he didn't want reverb, nor channel switching, or solid-state EQ ... just a pair (or two) of screamin' 6L6's. a stock Mesa Boogie Mark I with dymo labels! and I have to admit, that there was a quality that always felt adulterated when trying to get more complexity out of something so pure and simple.

I guess that is how I am feeling about my Drakes. they don't do everything, but when you turn them to '11', they crank and are a blast to play.

Hi Brenton Crowhurst,

I know I'll probably be burnt at the stake for this, but you have posted an interesting line of thought.

My day to day radio is a Yaesu FT-450. It's small, light weight, hears well, has an excellent DSP (for the price), and the transmitter seems to do everything that is expected. Not to mention that it has all those modern things that make it a great tune-and-go radio <grin>. My only complaints are that the built-in speaker is complete rubbish (but nobody relies on the internal speaker anymore anyhow, right)? And the adjacent QRM figure could be better.

But when I really want a treat, and can appreciate the audio from a tube rig, I switch over to my TR-4. It is cantankerous, I have to wait for a good stable warmup, scares the heck out of me when I see a "tune-up" at 200-watts (on a 40-year old radio), and I can use it to warm my coffee (sometimes can make coffee if I'm talking a long time <grin>).
But the noise blanker in it is the best I've run into, the audio is simply gorgeous, and the transmitted audio from it (via my Shure 450) is said to be just beautiful. Anything I can hear on my Yaesu, I often hear at least as well on the Drake (I think the quieting curve is better on the Drake), and QRM from adjacent signals is just plain nonexistent. And it is not as subject to certain kinds of ground-phase electrical noises as my solid-state radio, because of the relatively higher voltages running around in it.

And there's another benefit, both radios need 300-watts for transmission. But the Yaesu makes 100-watts PEP, while the Drake TR-4 will make almost 200-watts PEP. And that sometimes helps on noisy nights <grin>!

And lest we forget, I have about $1000 invested in my Yaesu station. I have about $500 in my Drake station (TR-4, RV-3, AC-4 [rebuilt]). If I had known the price differential, when I started, I might have gone tube radio when I started <grin>.

4054. RE: [DrakeRadio] comparing Drake equipment to Collins ...

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-01 01:21:57 UTC
From: Brenton Crowhurst
Topic: 4034 Message: 4054

Well, Fellows,

I'm really enjoying all your thoughts -- some of you have chanced a flaming to give a response, and yet, none has yet even suffered even a scalding from a hot tube!

Richard's post got me thinking, on account of a few things that led me to Drake.

Last year, I "updated" my hi fi by going ahead to the past: Dynakit power amp but with a modern driver board, and tube pre-amp and phono amp, and I've been thrilled with the "tube sound" of it.

I wondered, in getting back to this hobby if it could be similar? From reviews I was reading on eHam, I was getting the impression that DSP was not essential, that an outboard DSP filter could be quite good if I wanted to try it, and that the Drakes were still really great radios. Then I chatted with a couple fellows from the list here who strongly affirmed those views, so I was sold.

It's a quite a vivid picture Richard paints of self indulgent excess gadgetry that seems to be there for the sake of itself in some radios, without a really good concept behind it, or without adequate execution. Maybe I'm taking liberties with what he was saying about some of the would-be competitors with Collins. It gets back to my stereo analogy, what one of you said, about how does it sound, or how does it work? I woulnd't but a graphic equalizer in my stereo system -- for all that it's supposed to "do", at the end of the day, lots of folks think those things just introduce a lot of problems.

(Not that I'm taking a poke at any of you who might be into this ham audio equalizing gig.)

Very good discussion...I've even taken my hard hat off!

Audio...yes, audio is the most distinctive area where the Drake and Collins gear shine. My K3 is a performer. You can adjust every little thing from AGC rise and decay and audio spectrum to a 1000 other things. I like it. In CQWW on the low end of 40 or 80 (I don't do 160) it kicks absolute butt over anything I've ever used. The filters and AGC are outstanding.

Now on to the audio....into a quality set of headphones the audio is very good, clean and clear. But, through a speaker I'd have to say (for whatever reason) it is not so good and compared to listening to the 75S3C or an R4C (or my 51S1), it is not magical. I am fortunate to have both. To me, there is no more pleasing sound than to listen to my old tube gear on a signal over the North pole with arctic flutter. It is magical. The K3 out performs and is truly superior but when the dials on a old Collins or Drake are lit up and the magical sound is coming through that speaker, well, it is truly magical. But, for serious operating....the K3 is the obvious choice.

It also amazes me how many old radio guys are guitar guys too. I have 2 beautiful old vintage guitars that I play regularly and a couple from the present era :-)....

OK, I've weighed in and now I'll check out..

Happy Trails

I've heard good things about the K3, but I have never had the chance to operate one. I would welcome a modern radio that is as pleasurable to operate as a vintage Drake.

What it's all about for me is the receiver. How does it sound, how does the AGC work on your ears, how easy is it to dig signals out of a crowded band, do the electronics "get in the way" of the signal? How do you feel after several hours

of contesting? Leaving a rig with a splitting headache is enough to turn one off to a brand for years. The Japanese seem to have problems getting the ACG right, and the signals sound all squashed up against a glass wall to me (I'm leaving Ten-Tec and Elecraft out of these comments as I have no experience with them). On a decent vintage rig, the band "breathes". There is space between signals. The audio is easy on the ears. Maybe recent offerings have gotten better, I don't know.

This presentation by Rob Sherwood is interesting reading:

http://www.sherweng.com/documents/Dayton2007w.pdf

Some of you have seen this already.... :)

On the transmit side, they also tend to do the ALC wrong in newer rigs, as described here:

http://www.sm5bsz.com/dynrange/alc.htm

Makes me want to run right out and buy one! I remember hearing tales about hams spending literally hours and hours tweaking and tuning to get the best sounding, cleanest possible signal on the air. Now, it seems the tendency is to just buy a box and hook up an antenna.

Bells and whistles are sure cool, but I wonder how much of that stuff most people really use?

So, how does it SOUND?

73

I've owned a KWM-2A and a TR4CW. The one thing that bugs me about the Drake is it tunes backwards on all bands except 20 meters.

4059. Need some Informations for Drake Parts

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-02 22:20:52 UTC
From: Hans-Joachim Empel
Topic: 4059 Message: 4059

Good Afternoon to the Group ,

i am writing from Germany and i need some Informations for some Drake Parts.

I am owning a Drake SPR - 4 Receiver in excellent conditions.

For this receiver i am looking for a frequency synthesizer like the FS-4 ore a modern version of the FS - 4.

Also i am looking for a frequency counter for my SPR - 4.

If somebody can give me some informations how to buy this parts , i am verry happy.

Here in Europe its nearly impossible to get some Informations for buying this parts.

EBAY is not the way the most parts are much to expensive ore in not that good quality.

The SPR - 4 is a great receiver and in some parts better as all the modern receivers.

With the FS - 4 and the Freq.Counter i want to modify my SPR - 4 and will use this receiver for another long periode.

Every Information is welcome.

Thanks for the help

Kind Regards from Germany

Joachim

From: phil_ad5x
Topic: 4060 Message: 4060

Just joined the group, so I don't know if this has been mentioned before. If you plug a 14.1 MHz crystal into the "C" socket, it'll get you 30 meters (10.5-10 MHz) and 17 meters (17.5-18.2 MHz). The 2B is a great receiver.

I've also just added a QSK T/R switch construction project in the "Articles" section of my website (www.ad5x.com) that is easy to build and works great. I use it with my Johnson Ranger/Drake 2B set-up.

I get all my crystals from ICM, www.icmfg.com. Great bunch of folks. Just tell them it is for a Drake 2B (or whatever radio you have) and they'll provide the exact crystal necessary with all the correct parameters.

4064. L4PS serial number

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-04 14:27:03 UTC
From: David
Topic: 4064 Message: 4064

Hi, I'm looking for an answer to a nagging question: My L4PS sn is 142X. This sn is not consistant with the standard sequence of at least 4 numbers I've seen and there are no "x's" shown on the wb4hfn web site. Anyone know the answer? Is this an early or late supply? Mine works fine, and I've rebuilt it a couple years back with new boards, caps, resistors and all from Harbach. Just curious about the sn.
Thanks,
David

From: w1fued@sbcglobal.net
Topic: 4065 Message: 4065

Ok, its not a Drake question, but I bet a lot of you will know the answer

What color was the cabinet of the Jonson 122 VFO?

I have picked up one for use with my 2-b and Johnson Adventurer and the cabinet is (a beat up) black wrinkle paint. Was this the original finish or was it Johnson color and been repainted?

Thanks,
Ed

Hello David,

The "X" in the serial number is usually an indicator that the product is a prototype model, or a product made to remain in house for testing or demonstrations, etc. If I remember correctly the "X" in the L-4PS serial number indicated it had a different power transformer.

Mine was a nasty black wrinkle also. At least what was left of it. Large areas of the paint had fallen off.
I could find no indication that any primer had ever been applied.

I might add. I have three of them here. They are all original and maroon in color. E.F. Johnson used this color on most of their boat anchors until they switched to a medium gray color. Some of their gear had a wrinkle finish and others had a smooth surface but still maroon in color. The Viking l had a wrinkle finish and used this VFO however, the Viking ll which also used this VFO had a smooth maroon finish.

Lee -

Agreed. The problem is that the original paint was so poorly applied
that a large percentage of Johnson gear has been repainted. I was
convinced that the Viking I was black wrinkle because the first FOUR I
saw 'in person' were black wrinkle!!

I have three or four 122's, and only one is the maroon color. The
maroon could easily be mistaken for black when it's really dirty!!

Plasti-Kote GM7191 is a close match, NAPA or other auto supply store.

Duplicolor "GM 353 Dark Red M"

or

Sherwin-Williams

oz 32 64 128
B1 Black - 22 - -
R3 Magenta - 6 - -
R4 New Red - 8 - -

I found that Rustoleum Painter's Touch Kona Brown Gloss #1977 spray paint (available from Home Depot) is an EXACT match to the original paint used on the Johnson cabinet. I repainted my Johnson Ranger cabinet with this and it looks new.

I'm working on an earlier version R4C receiver (3 MODE switch filter settings). It wasn't taken care of by one or more previous owners, which is to say it's in fair condition.

Does anyone have a spare top cover from any of the R4<any>/T4X<any> series receivers and transmitters they would consider selling?

Joachim -

The AADE DFD1-Drake would work for a digital readout at $50 for the kit.

<http://www.aade.com/#dfd>

I don't know of a direct replacement for the FS-4. There were not many
sold originally, so the few available demand a fairly high price.

One possibility that might be modified to do the job would be the K5BCQ
Kit #2

<http://www.qsl.net/k5bcq/Kits/Kits.html>

It would require a little modification and packaging, but I believe
would work just fine. At $40 for the kit, it's considerably cheaper
than an FS-4!

Not too bad a deal since the AADE DFD1-Drake would cost 37,93 Euros and the K5BCQ Kit-2 would be 30,34 Euros. Of course then you have to add in the USPS and if you pay via PayWow the sky is the limit.

4078. SPR-4 and Frequency Synthesyzer

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-07 10:45:03 UTC
From: Hans-Joachim Empel
Topic: 4078 Message: 4078

Its me again , Joachim from Germany.

I need some Informations from more experianced OMs as me.

I found in the Internet following DDS Generator from a german Supplier .

Please see the datas below , i think the most important datas i translated in english.

Can i use this DDS - Generator to make my SPR - 4 fully available for Shortwave like the FS - 4 ??????

Every Help ore Iear ore Information are wellcome , also if somebody has a usable DDS - Generator to sell , please let me know !!!!!

Thanks fromGermany

Joachim

DDS - Signalgenerator , Signalgenerator
Beschreibung:

DDS - Signalgenerator mit einem Frequenzbereich von 0Hz - 89MHz. (Frequenvy Range : 0 - 89 MHz)

Alle Funktionen des Signalgenerators werden mit Hilfe einnes PC's gesteuert. (Computer controlled (PC)
Die Schrittfrequenz ist durchgehend in 0.040Hz (40mHz) Schritten einstellbar. (minimal Step 0.040 Hz)
Der gesamte Frequenzbereich kann so in 2.4 Millarden Schritten durchlaufen werden !!
Die Ausgangsspannung ist einstellbar von 0 - 1.5Vss (Output Voltage : 0 - 1.5Vss)
Der DDS - Signalgenerator besitzt einen Wobbler. Die minimale Startfrequenz liegt bei 0Hz, (min Freq . 0.0 Hz)
le Endfrequenz bei 89Mhz. Auch hier ist der kleinste Schritt im gesamten (max Freq. 89.00 MHz)!

Der Generator ist mit Hilfe einer Steuerdatei (steuer.ini) fernsteuerbar. (REMOTE CONTROLLED via PC / LAPTOP)

Dank der DDS-Technologie besitzt der Signalgenerator hervorragende technische Merkmale

Merkmal Minimum Typisch Maximum
Frequenz 0 - 89MHz
Frequenzschritt 0.040Hz !! - 89MHz
Ausgangsspannung 0 - 1.5Vss
Ausgangsstrom 0mA 20mA 30mA

Lieferumfang: Delivery of Parts
- Deutsche Beschreibung (German Manual)
- DDS-Signalgenerator (DDS Signal Generator)
- Netzteil (Powersupply)
- Anschlusskabel (Cabels)
- Original Software (Vollversion). (Software for PC full Version)
- Anschluss PC: parallele Schnittstelle, LPT1 (onnected on PC LPT-1 Port)
Getestete Betriebssysteme: Windows 95b/98/SE/ME/NT/XP/2000

unfortunately, the company that made new panels is no more. at least, they haven't returned my dozen inquiries. and so, I must attempt to touch-up a few areas on my RV4C panel.

has anyone found a good match for the dark grey? the darkest grey paint I have found was Krylon Smoke Grey which is still too light. I realize that results are generally poor, but in this instance, I could hardly make thing worse.

Krylon, Rustoleum, spray or brushed?

You might check if a place like Home Depot or an
automotive supply store could match the paint. They can
often match all sorts of special colors.

Daniel -

Yes, he stopped some months ago. Guess he got 'burned out'.

There are a couple of Testor's or ModelMaker paints that come very close.

The Dark Gray is #1791 'Navy Gray', and the Light Gray is #1794 'Agressor Gray'. They can of course be darkened or lightened to allow for aging by adding a little black or white if necessary.

The secret to 'touch-up' success is to 'rub in' the spot to the surrounding area so you don't have a 'bump' of new paint. 600 or even 1000-1500 grit 'wet/dry' sandpaper, and finish with something like Novus #2 or toothpaste, etc.

The Cabinets are Rustoleum #7777 'Satin Black', or Krylon #1613 'Semi-Flat Black'. Either is fine for the early, smooth cabinets, (up through the "A" series,) and there is a good article for simulating the 'textured' finish found on the later "B" and "C" series at

<http://www.wb4hfn.com/DRAKE/DrakeArticles/TechTips/CabinetRepainting.htm>.

Of course there's always Hartzell Mfr Co., who will still repaint (powder coat) and even screen the TR-4 cabinets. Unfortunately, last I heard they charged $50 per _piece_ (top and bottom), plus $25 shipping and handling.

thanks, I'll order the paints online. it's a shame Tony quit making panels. I would pay dearly for a RV4C panel. every panel I've managed to locate and buy is sub-par ... the good news is that I now have two RV4C's that are working perfectly.

4083. PTO drift ... 1khz in 20 minutes

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-08 21:23:02 UTC
From: arsnf7z
Topic: 4083 Message: 4083

before tearing into the PTO on my R4C, I'm thinking someone else has experienced this before me and might point me directly to a common component that fails in this manner.

in twenty minutes, after a 20 minute warmup, the PTO drifts about 1khz, far out of spec. I can lock the carrier oscillator from the T4XC and the transmitter PTO is very stable, whereas the R4C takes off into the wild blue.

is this perhaps, a common problem?

thanks,

NF7Z, daniel

Is it a 'smooth' drift? Or is it "jumping"? Which way? Is it the PTO,
or is it the BFO that's drifting?

'Tearing into the PTO' is not likely to resolve this problem.

What is the 'reference' signal that you're using?

What is the DC supply to the PTO doing?

nothing scientific on this end. it is a smooth, continuous drift, such that a 80 meter signal will appear to drift 'up' in frequency. in other words, to chase the reference generator I have to continually tune to a higher frequency. I've no schematic and can't remember the oscillator/mixing chain. my first approach is to monitor the DC voltage that comes off the zener. the receiver has all original components with zero modifications, which also means, all the original electrolytics. however, since this drift is so severe, I was hoping that someone had had the same problem and identifiifed the failure.

I was trying to think what parameter could change to manifest such a large drift. it seems to me that if the BFO drifted, it would be associated with a passband shift, which does not occur.

I appreciate your thoughts ...

First, how certain are you of your 'reference' stability?

The 3rd Mixer LO in the receiver is crystal controlled when in Separate. The C-Line patches the CAR OSC signal from the Transmitter to the Receiver 3rd Mixer in transceive. The PreMix signal (difference between the BAND oscillator and PTO is also patched to the Receiver via the INJ cable, so these are the signals 'eliminated' from the suspect list when you transceive under TX control.

The Receiver 3rd Mixer oscillator has a trimmer cap which could be suspect. There is a separate trimmer cap for AM.

C165 electrolytic on the +11V power supply is a possibility if it's leaky enough to drag the 11V supply below the PTO Zener CR6 as it heats up. C151 is inside the PTO, but it is a tantalum, and considerably more reliable than the electrolytic.

The only PTO 'drift' that I've run into is a bad FET, Q8, but that typically presents as a 'jitter' rather than a slow, steady drift. Opening the PTO is a little risky since the TC and linearization components are sometimes just hanging in the air, and disturbing their position can be catastrophic. The only things I have been able to replace without harm are the Zener and the FET. The PTO is really not designed for repair! :-)

A 1 kHz change in the BFO frequency might not change the Passband tuning enough to be apparent unless you were on a narrow bandwidth filter.

I'd verify the reference stability and if it's good then the Zener voltage. Beyond that I'd suggest a counter before getting into the PTO. The PTO and BFO are the only two oscillators that are NOT crystal controlled, and though crystals 'can' drift, it would be very unusual for one to drift in this fashion.

One last question. Does the frequency continue to drift upward, or does it eventually 'stop' drifting and stabilize?

thanks Garey for your comments. I was confident this was a typical failure mode (seen dozens of times) but apparently I've got myself an interesting patient. well, I'll just have to dig into the R4C. as I have mentioned before, I am on my sailboat and slightly less motivated to get out the soldering iron! I did manage to download the schematic so after sailing to Port Townsend this morning I'll give it a go.

there are several things I can try, and I do have a counter to help characterize the drift. it does tend to stabilize after about 1khz drift. the signal source I use is a new Tektronix AWG3021B that is synthesized and quite accurate. again, when running in transceive mode with the T4XC I can determine that the transmitter PTO is stable and the R4C is drifting madly by comparison.

as I remember, drift at the BFO would not cause a shift in frequency. the 50khz is mixed twice, once in the last mixer, and then in the product detector. the result being a passband shift across the filter in use. I'll measure the PTO voltage first, and then hang the counter on the PTO and better characterize the instability.

I was hoping someone would simply say 'yeah, seen it happen. it's C999. goes sour all the time'. oh well .. no such luck!

if all else ultimately fails, I have a spare RV4C PTO that is rock solid that I can substitute. however, there will be a great satisfaction if I can get the original working properly.

thanks again,

daniel

Daniel,

I had a problem with my R4C that is similar. I installed a 12 volt DC power supply for the VFO and changed the zener to a 5-watt and putting in a reverse bias silicon diode which is a voltage reference. I do not remember the zener voltage rating but I think I took into account the diode which is .7 volts to make the change. I no longer have any drift to speak of. I do have a diode in the receiver I need to change as the sensitivity is not what it should be.

73,

Ron, K0IC

From: Garey Barrell
Topic: 4083 Message: 4091

This is not a bad approach. The 5W Zener is way overkill, the Zener only dissipates 200 mW. The 1N714 is rated at 250 mW, but if the actual Zener voltage is higher than the nominal (+/- 10%) of 10V it is bumping up against the rating. A 1N4740 would be a good replacement, with plenty of margin at 1W.

I suppose the input voltage could be picked off of the +12 or +14V supply in the R-4C, but I'm not sure it's worth it. The Drake method of using a resistor from a much higher voltage gets a lot of grief, but it actually approaches the 'ideal' source for a Zener, i.e., a pure current source. Which is why Drake engineers used this circuit even in the C Line where they had lower voltages available.

The voltage stability of the 1N47xx series Zeners is good enough that the additional forward biased junction could even 'upset' the temperature stability with it's 1 mV / 1?C tempco.

All of which revolves around the voltage measured on the DC input to the PTO to determine if that is what is causing Daniel's problem. The absolute voltage is obviously not as important as the delta V over time.

4092. T4XB PTO removal

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-10 13:09:08 UTC
From: w5rkl
Topic: 4092 Message: 4092

Good morning everyone,

I recently purchased a T4XB that has no RF output. The problem turned out to be no output from the PTO. I verified this by using my R4C as the PTO source (Injection connection between the R4C and T4XB) and the transmitter works. The transmitter tunes up with 100 watts output on 40 meter CW. The keyed note sound clean and stable in a separate receiver.

I looked the wiring over at the bottom of the PTO wiring access hole and nothing initially appears to be broken or tampered with.

My initial thought is PTO Q2, MPF-102, has failed which would require either removing the PTO or removing the outer metal cover.

I repaired my R4C PTO a year ago, diode lead came loose from the circuit board inside the PTO. I didn't remove the PTO to fix that problem, just the outer metal cover.

There is a modification to V1B, AGC amplifier, where a previous owner installed a small toggle switch mounted in the right rear hole between R12 (1.5K) and pin 7 of V1 and R29 (22K). The switch appears to turn V1B ON and OFF. That will have to come out.

Any suggestions?

73s
Mike

Mike,

be advised that the Injection output from the R4C is not simply the PTO signal (it's mixed with band-select oscillator). therefore, you can't necessarily indict the PTO just because it works with the receiver.

Mike -

Daniel already pointed out that the INJ signal is the _difference_ of the BAND oscillator and PTO, so either 'could' be missing. Of course there could also be a fault in the PreMixer itself.

Verify that you have ~11 VDC on the 'red' wire that goes inside the PTO. You should have about 2V p-p on the 'wht' wire at ~ 5 MHz.

A shorted Zener is also a possibility. Depending upon the unit serial number, the PTO could be either a 2N706 -or- an MPF102. A 2N5668 is a better choice as a replacement for the MPF-102.

Let us know what you find!

Okay, I'll go sit in the corner with the "Dunce" hat on....:) Duh....

The PTO is working fine and the 5645Khz carrier oscillator is also working, it's oscillating at 5644.7, frequency taken from the Carrier Balance pot wiper.

I checked the output of Q3 Het oscillator as it feeds to pin 1 of V8 and I only see the PTO frequency. I'll have to check if I have any. I have 2N3393s but I don't think I have 2N3394s.

I 'assume' this is on more than one BAND (crystal?)

Switch DeoxiT'ed?

Q3 should have 1.1VDC on Emitter, 1.7 V on Base and 7.8 V on Collector.

4099. Re: T4XB PTO removal

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-10 15:38:07 UTC
From: w5rkl
Topic: 4092 Message: 4099

Okay, after checking all of the oscillators, here is what I found.

1. Carrier oscillator is working.

2. The PTO is working

3. Q3 "is" working BUT I'm having troubles with the het crystals oscillating.

Item 3 may be dirty crystal sockets. I cleaned the crystal select wafer switch.

For a test I pulled the 40 meter het crystal from a spare R4C and 40 meters works. I then put the original crystal back in and 40 meter worded. "BUT", I don't want to jump to conclusions and make a decision on the crystals. So, I'm continue to troubleshoot the het oscillator circuit so I'm absolutely sure.

I'll let you know what I end up finding as the problem.

4100. Re: T4XB PTO removal

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-10 17:30:52 UTC
From: w5rkl
Topic: 4092 Message: 4100

Afternoon everyone,

Okay, after thorough testing I found the heterodyne oscillator is working. I did, however, find the 40 meter heterodyne crystal is bad, it won't oscillate. I had a spare so I replaced it. Now ALL bands work. The transmitter could stand for a slight touch up in the alignment. But, for now, The transmitter's working. I connected the transmitter to the R4C receiver and it controls the receiver.

I cleaned the crystal sockets, all wafer switches, and checked each crystal to ensure the pins were making contact in the crystal sockets. I also cleaned the VOX pots, Drive pot, and blew out all of the dust balls. Pulled all the tubes and cleaned the final amplifier and the chassis as much as I could. Unfortunately, the copper chassis has quite a bit of discoloration but fortunately, no rust. I still need to remove the toggle switch modification on the rear panel that appears to turn the AGC amplifier V1B on and off. Don't know why this was done but it's coming out.

Thanks for all the suggestions and also for Bill and Gary for showing me I was looking in the wrong place.

For $220 which included the transmitter, AC3 supply, and MS4, I guess it wasn't a bad deal after all. No real expense in repairs, just time and a spare crystal.

Boy, am I glad I decided to pass on that purportedly nice, clean complete 4B set offered for the modest price of, ohhh, $1200, I think he wanted.

Subject: [DrakeRadio] Re: T4XB PTO removal

Afternoon everyone,

Okay, after thorough testing I found the heterodyne oscillator is working. I did, however, find the 40 meter heterodyne crystal is bad, it won't oscillate. I had a spare so I replaced it. Now ALL bands work. The transmitter could stand for a slight touch up in the alignment. But, for now, The transmitter's working. I connected the transmitter to the R4C receiver and it controls the receiver.

I cleaned the crystal sockets, all wafer switches, and checked each crystal to ensure the pins were making contact in the crystal sockets. I also cleaned the VOX pots, Drive pot, and blew out all of the dust balls. Pulled all the tubes and cleaned the final amplifier and the chassis as much as I could. Unfortunately, the copper chassis has quite a bit of discoloration but fortunately, no rust. I still need to remove the toggle switch modification on the rear panel that appears to turn the AGC amplifier V1B on and off. Don't know why this was done but it's coming out.

Thanks for all the suggestions and also for Bill and Gary for showing me I was looking in the wrong place.

For $220 which included the transmitter, AC3 supply, and MS4, I guess it wasn't a bad deal after all. No real expense in repairs, just time and a spare crystal.

Brenton -

Well, IF all the copper is _perfect_, all the _paint_ is perfect,
the knobs, dials, tubes, all original, no modifications, all manuals,
etc., etc., etc., that price is not TOO far off. A typical set should
bring $6-800 if unmodified and with only a few minor copper blemishes,
good knobs and dials all present and accounted for.

But if you don't care how it looks, corroded copper, scuffed paint,
dented cabinet, rusty chassis, etc., you can get a set for a LOT less.

TYPICAL prices these days are about $275-325 for the R-4B, $150-200 for
the T-4XB, $100 for the AC-4, and about $60-70 for the (originally $20!)
speaker.

Of course there are always the "lost interest", "distress", or "estate"
bargains, and even, rarely, a dumpster or trash day find!

Just uploaded pictures of the T4XB, MS4, and my older version R4C.

Again, thanks to everyone for their comments, suggestions, and support. All I need to do now is rebuild the AC3 supply and mount it in the MS4 speaker enclosure.

Looks good Mike! That's a Version 2, so should have the MPF-102 /
2N5668 in the 'FET' PTO.

I can't think of any 'good' reason to disable the ALC.

Jim -

I know your type..... They find a complete B-Line, in the original boxes and with all accessories, sitting on the curb on trash day. When they get them home, they open the previously unopened plastic bags inside and take out a perfect unblemished set.

I don't want to hear about it. Don't ask, don't tell!! :-)

Hello Garey & Mike,

A lot of 4-lines were used by CB'ers back in the day. And they liked to see that meter bounce, so they would disable the ALC. Either with a switch or by cutting off a pin on the ALC amp, which would cause them to purchase a new tube when run through Drakes service department !! HI HI Another way was to put a shorting plug in the ALC jack on the AC-4. Those shorting plugs were usually lost in the service department and never went back with the power supply. HI HI The 38.1 crystals were also removed, but sent back in a coin envelope.

Hi Bill -

I wondered about that..... :-) That was the only 'reason' I could
think of.

While you're here, do you have specifications for the crystals for the
2-B, 4-Line, etc.??

I guessed Parallel Resonant @ 32 pF load for those, and Series Resonant
@ 20 pF load for the overtone ones. Was I even close?

Hello Garey,

Crystal Specs,
4-line/TR-4:

+/- .003% frequency tolerance
Series resonant
Hermetically sealed HC-6/U plug in holder
Series resistance less than 30 ohms

2-C Accessory Crystal: which I think was same for 2-A/2-B

+/- .005% frequency tolerance at room temperature
Series resonant
Series resistance less than 30 ohms
Hermetically sealed in HC-6/U plug in holder
Lower frequencies are fundamental, upper frequencies can be third overtone
Range 7.000 to 27.500 MHz
The 2-C range crystals were +/- .003%

73, Bill

Ohhhhh. Maybe I shoulda snapped it up. It was reported to be very clean with near glistening copper -- I think -- it's copper inside, right? (yeah, take me out and shoot me).

I come to appreciate tubes more and more with time. Probably something Freudian about that. Or, maybe "Kleinian".

I'm going to have to have one of these radios... I mean two of these radios sooner or later.

Brenton -

Well, IF all the copper is _perfect_, all the _paint_ is perfect,
the knobs, dials, tubes, all original, no modifications, all manuals,
etc., etc., etc., that price is not TOO far off. A typical set should
bring $6-800 if unmodified and with only a few minor copper blemishes,
good knobs and dials all present and accounted for.

But if you don't care how it looks, corroded copper, scuffed paint,
dented cabinet, rusty chassis, etc., you can get a set for a LOT less.

TYPICAL prices these days are about $275-325 for the R-4B, $150-200 for
the T-4XB, $100 for the AC-4, and about $60-70 for the (originally $20!)
speaker.

Of course there are always the "lost interest", "distress", or "estate"
bargains, and even, rarely, a dumpster or trash day find!

The 1-A, 2-A/B, R-4, A and B Series radios are all copper plated steel chassis. On the plus side, it is B-eautiful when it's perfect, but you hardly ever see one in that condition any more. If you look UNDER the chassis, you'll see what the top 'usta' look like! :-)

But, it's a very, very thin copper plate, and the lacquer that they put over it is a., also very thin; and b., probably dipped or sprayed with resultant little bubbles that popped and exposed copper to the air. Of course I doubt seriously if Drake expected these radios to still be in use 50 years later!

I haven't seen a 'perfect' one in quite a few years, which is what I would expect from ones that expensive. I believe it would be necessary to find a set that someone bought in the 1965, then lost interest and stored them in a closet wrapped in the original plastic and boxes until last week.

The good news is that the copper is not visible in normal operation, and has absolutely no effect on function. There are those that look like they were stored UNDER the chicken coop (I'll NEVER understand how someone could do that) for the last 50 years. But I bet if they were cleaned up properly they'd work just as well as the 'pretty' ones! :-)

4115. LC2 Dx Engineering speech processor for T4XC

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-11 15:11:51 UTC
From: inferno7654
Topic: 4115 Message: 4115

Hello,

i am new to group.
My name is Graziano and my callsign is IW2NOy, i also own a USA callsign and is W2NOY.
I am Drake fan and i recently buy a complete Line 4C, composed by R-4C and T4-XC with MS4+AC4.
Some month ago i found in ebay the LC2 speech processor made by DX Engineering for the T-4XC. I installed the speech processor box on the rear of my T4XC and remove the tube (12BA6) from the socket V2 to plug the socket coming from the Speech processor box.
Following the instruction manual (a bit unreadble), if afterthe installation you see a very low gain moving the XMTR GAIN knob during the tuning, you have to tune also the T2 !
T2 is a smail "squared-iron-box" very close to V2, is in the upper left corner near the final tube cage.
There is a hole on the top but i cannot figured out how tune this T2.
The manual speak about a "tuning tools" but i cannot understand what is speaking about.
In short, i need to put the XMTR GAIN near .15 amp of plate current and tune the T2 until i get the maximum plate current, to complete the installation and to get a XMTR GAIN working as it should be during tuning.
Anyone can help me ? Ideas ?

I am sorry, i am novice with Drake equipment.
I hope that my english is good enough to let you understand my problem and explanation that i wrote.

Thanks a lot to all, best regards, 73's de IW2NOY-W2NOY

Dear Mr. Mike.

May I humbly suggest that instead of you taking your Collins radio equipment "to the grave" that just before your demise (may it be far into the future) you select some humble, poor, struggling, but VERY appreciative ham radio operator to either bequeath or sell your equipment to. As you can guess, I know of one such individual who would lovingly take care of this equipment. (smile)

On a serious note, how many of us have a plan for our families to follow for the disposal of our equipment after our deaths? Even if the plan is as simple as contacting a specific ham friend who would appreciate the radios we have, it might save some very fine equipment from going into a landfill.

4121. Drake 2-a Crystal Calibrator. Socket

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-14 13:58:21 UTC
From: w1fued@sbcglobal.net
Topic: 4121 Message: 4121

I have had my 2-a quite a while without a crystal calibrator. I recently bought a 2-ac calibrator, which has the standard 4 pin plugin base. The schematic for the 2-a shows a 4 pin socket as well. However, my 2-a has a large octal socket for the calibrator. I can of course, modify the calibrator for use, but the question is....

Is the large octal socket standard on the 2-a rx.? It sure looks original....then I guess they sold the calibrator with two different plugs over the years?

Thanks,

Ed

Lee -

I don't think I've ever SEEN a T-4"C". The T-4 is relatively rare, and
I've only seen ONE T-4B in the last 50 years! :-)

There weren't many changes in the T-4X from the first to the last of the
series. The T-4, was just a T-4X with the PTO and BAND oscillator left
out. The PreMixer signal from the R-4(any) was brought in through the
INJ cable just like the T-4X for 'transceive' operation.

I suspect if you take a T-4XC schematic and just take out the PTO and
BAND circuitry, you'll have about 98% of a "T-4C" schematic!

Ed -

The earliest 2-A manual I have shows the four pin CALIBRATOR socket. I don't have any record or information regarding a octal based calibrator from Drake. I suspect yours was modified to take one of the many octal based calibrators used in earlier receivers from other manufacturers.

I've been wrong before! :-)

From: Garey Barrell
Topic: 4120 Message: 4124

Paul -

It should work fine. It MAY be necessary to short out R2, or reduce it's value, but not likely. Early 2-NTs had a 4.7k at R2, but it was reduced to 680 ohms to increase gain. The 122 should have plenty of output. Be sure the "hot" VFO lead goes into the correct Xtal socket pin! (It's the one on the right....)

Topic: 4120 Message: 4125

Thanks, Garey. I currently have neither piece of equipment on hand so was just asking, but.....I have owned & used several 122 VFOs with Viking II & Adventurer transmitters, Eico 723, etc., so I am aware of the interface modifications required in those various applications. I once had a 2NT for a short time but didn't use a VFO.

There are a couple of keying options that can be used with the 122 and with the Adventurer I was able to construct a control box that allowed me to select VFO keying (which I don't recommend except on 80m) or transmitter keying with the VFO running all the time. I used a single TX/RX switch to switch the antenna, mute the receiver, provide a sidetone, etc., etc. BUT since the 2NT has what amounts to a break-in keying system with sidetone oscillator the implementation should be simpler.

Now I just need to find a 2NT, and later to decide what VFO I'm going to use. Hmmm, maybe I'll just build one of the latter..... :-)

73/arf,

Paul, K4MSG

Dear Mr. Mike.

May I humbly suggest that instead of you taking your Collins radio equipment
"to
the grave" that just before your demise (may it be far into the future) you
select some humble, poor, struggling, but VERY appreciative ham radio
operator
to either bequeath or sell your equipment to. As you can guess, I know of
one
such individual who would lovingly take care of this equipment. (smile)

On a serious note, how many of us have a plan for our families to follow for
the
disposal of our equipment after our deaths? Even if the plan is as simple as

contacting a specific ham friend who would appreciate the radios we have, it

might save some very fine equipment from going into a landfill.

73.

Mike -

Best bet is the Drake 'upgrade' kit. I don't know if John Kriner has any of them left or not. Small PC board that mounts over the feedthrough insulators of the old relay, and has the 'standard' P & B plug-in relay, R10-E1-Y4-V2.5k.

What a great idea! Take your Drakes to the grave and use the Collins

equipment to pay for the burial ceremony..

Of course this wouldn't work if you opt for cremation.. J

Subject: [DrakeRadio] Taking Equipment to the Grave

Dear Mr. Mike.

May I humbly suggest that instead of you taking your Collins radio equipment

"to

the grave" that just before your demise (may it be far into the future) you

select some humble, poor, struggling, but VERY appreciative ham radio

operator

to either bequeath or sell your equipment to. As you can guess, I know of

one

such individual who would lovingly take care of this equipment. (smile)

On a serious note, how many of us have a plan for our families to follow for

the

disposal of our equipment after our deaths? Even if the plan is as simple as

contacting a specific ham friend who would appreciate the radios we have, it

might save some very fine equipment from going into a landfill.

73.

I know that Unique Radio Parts closed up shop a couple of years ago, but they used to sell filter cap boards + caps to replace the can caps in the R-4 series and 2B receivers.

Does anyone have a mask or template of the actual board(s) that I could use to etch my own one-off PCBs to replace the cans in a 2B and an R-4? I understand that we're no doubt talking about two different PCBs for the two receivers.

Also, does anyone know of a source of the blue light-filtering material for the R-4 series dials?

TNX in advance.

Hi Garey,

I'm not familiar with John Kriner's relay upgrade.

I have a new R10-E1-Y4-V2.5K 4PDT relays. Isn't the T4XB relay a 250VDC coil relay or am I misreading the T4XB schematic? This relay is a direct drop in for the relay in the T4XC transmitter, I have one plugged into the T4XC relay socket that replaced the original Drake relay. It works very well.

I also have a Magnecraft 4PDT 782XDX3C relay that is a replacement for the Heathkit HW-101 relay. The coil resistance is 15.7K but the coil voltage is 240VAC/30VDC. The T4XB and HW-101 have the relay coils in series with the plate of the relay amplifier with 250VDC on the T4XB and 300VDC on the HW-101.

I assume that John's upgrade kit had a 4PDT relay socket mounted to the small PC board, the R10-E1-Y4-2.5K relay plugged into the socket then mounted as you said, then connected to the appropriate wires, is that correct?

An alternative for the caps are being made by hayseedhamfest.com
This drake user makes replacement caps for drake equipment. they fit like the original cans do. I used replacements in my Tr4 and r4B with good success.

Blue material usually comes from a stage lighting supply house like eclipse lighting or barbizon. I have some of the plastic that comes in large sheets but is thinner than the original. I'm sure that someone else on this forum will have the number of the Lee filter material as its called.

Truth be told, only one of you should have purchased, then cut the sheet
into equal pieces for all who wanted. You are only going to use a very
small corner of that big sheet!
And you will have lost the roll of gel by the time you decide to replace the
faded blue film again! <GRIN>

Vic.....

I am sure you can find a theatrical lighting supply house in Great Britain that can supply you with Lee filter gels. The Lee company is world wide and is based in Andover, Hampshire, England. Here is a phone number: (01264) 366245, FAX (01264) 355058.

Hello,
Is there anybody know where can buy the filp-flop IC 923 (IC1 and IC2). My R-4B marker doesn't work, it seem to be the ICs is malfunction.
I found a web site selling this IC, I sent an e-mail to him but no reply. The web sit is there : http://semiconductormuseum.com/MuseumStore/MuseumStore_Fairchild_923_Index.htm
I hope there have someone can help me buy this one.
Thanks,
mkchan

That is the only source I know of for the 923 ICs. He may be 'out'.

Have you checked the power supply for these ICs? It has two problematic electrolytic capacitors and supplies power ONLY to the Calibrator divider chain. Rectified and filtered from the filament supply.

4173. "New" 2B

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-18 16:50:32 UTC
From: phbjr@aol.com
Topic: 4173 Message: 4173

Just received Drake 2B s/n 2052. It's in quite nice condition for a radio of that vintage and seems to work just fine, plenty of signals audible and it is stable, no odd smells of overheating, etc. FP & cabinet are clean with only a few minor paint dings along the front edge of the cabinet. The chassis is clean, no obvious serious rust or corrosion, just that greenish patina that copper develops over the years.

The previous owner had the receiver for many years (although not the original owner) but used it only rarely and never had it serviced or aligned. For all I know it may still have all the original tubes (the ones I can see without removing the cabinet say "RCA").

Plan is to do some light cleaning of the cabinet & FP (very little required), install a re-cap kit, Deoxit the switches & pots, install a new tube set (keeping the old ones as spares), and touch up the alignment.

This radio is actually probably older than my first 2B, which I bought (IIRC) in '63. I've owned a couple of others since but stupidly let them get away, so this one is a "keeper". :-)

I have a sheet of Lee Filters "Blue Lagoon" #172.

I am happy to send pieces to anyone who would like some if you send me an SAE (A3).

Be warned though, that it is not EXACTLY identical in hue to the original.

Paul,
Just my opinion, and it's not worth a lot, hi, but I would NEVER replace a tube that is working in a receiver. I buy the "new set" to keep as spares and let the originals work as long as they want to. These tube sets are NOS as well as what is in your 2B right now, so as likely to be bad as the originals. Like I said, just my opinion, and didn't cost you a cent!! Touching up the alignment after re-capping is a good idea. Many old rigs have been "re-aligned" to mask other problems.
73, and enjoy your 2B. I have a nice one and rarely turn it on anymore. Just too many rigs, hi.

Don, in retrospect you're probably right about the tubes, i.e., if it ain't broke don't fix it. I'll buy one of the NOS sets for spares and probably pick up an extra or two of the rarest ones as well.

This radio included the original manual - a little dog-eared, to be sure - but it's always nice from the collectibility standpoint to have an original instead of a copy.

Wasn't thinking, should have known better (I grew up on tubes; I even know what an Eg-Ip curve is!). Check voltages & power supply ripple before starting; re-cap, check voltages & ripple again plus overall operation; clean switches, re-check; clean tube sockets ONE AT A TIME, re-check; touch up alignment carefully, re-check. Keep NOS tube set as spares if ever needed.

Don, Paul -

Agreed! IF you have 'new' tubes, there is nothing wrong with replacing an existing tube, readjusting the appropriate alignment, and seeing if the 'new' tube is better! If it IS better, decide if it's enough better to warrant the change, and put the 'other' tube in the spares stash. If no change, leave the original in place and know that you have a tested spare available.

The most troublesome tubes in the 2-B are the 6U8, (replace with 6EA8,) and the 12BA6s, which get 'gassy', sometimes even NOS. A 6U8 may result in a 'dead' 40M crystal, and gassy 12BA6s result in 'wandering' AVC. Also, don't let them sell you a 6BN8, it MUST be an 8BN8. If you want the reason why, see my article on WB4HFN!

Certainly an 'iconic' receiver, one of the best ever made by anybody!!

The Lee #172 is an 'identical' COLOR match to NOS blue filters from
Drake, back when they still had them! This film is slightly thinner
than the original, but the white diffuser provides more than enough support.

It's pretty close, but very slightly greener. It's also not as dark, but 2 layers fixes that.

2 layers is easy, as it's half as thick as the original.

Incidentally, my offer of free pieces is for the UK only, I'm afraid.

4184. Something for the 2B rivet counters

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-18 19:40:48 UTC
From: phbjr@aol.com
Topic: 4184 Message: 4184

Here's an interesting find - well, to me, anyway: #2052 does not have a little red button on the main dial so that it can be slid back & forth for calibration. In fact, the manual says:

"The dial scale is marked in 10 KC divisions and is adjustable for calibration purposes by sliding left or right with a slight pressure on the front of the glass."

IIRC, other versions I've owned that were no doubt manufactured later had a red button mounted on the front of the glass. Here's a photo from Wikipedia that shows it:

http://upload.wikimedia.org/wikipedia/commons/b/b5/Drake2b.png
(http://upload.wikimedia.org/wikipedia/commons/b/b5/Drake2b.png)

So, I wonder when it was added? I don't remember if my original 1963-purchased version had the button or not.

I love counting rivets..... ;-)

From: billykatzz
Topic: 4185 Message: 4185

I'm interested in hearing advice about what would be the optimum method of connecting my 300 ohm twinlead-fed 40 meter dipole to my Drake MN-4 transmatch, as the MN-4 doesn't have provisions for a balanced line feed.

Currently I have the twinlead attached to a homebrew airwound 4:1 balun, and then a short run of 213 coax into the shack to the MN-4. Loads up OK on most bands, but gets a little sketchy on 20 meters: the MN-4 drifts off-match the longer I transmit, requiring retuning.

Dave:

How short is short? I have about 12 feet going from the balun, running under my house and up into the shack. I hear it's bad to have the twinlead running on the ground.

4189. TR 7 quit

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-19 05:46:11 UTC
From: Craig Roberts
Topic: 4189 Message: 4189

Hmmm. My TR-7 quit transmitting tonight (just after a nice QSO with Italy). Relay pulls and all that, but there's almost no RF out. I can hear a very faint signal in an outboard receiver, but teh transmit output has got to be in the milliwatt range.

I let the rig cool for awhile and it transmitted for about 2 seconds when powered up and keyed, then -- dead again.

Receive is fine.

Bill,

Two observations:
1. It sounds like something (possibly the balun) is heating up and changing its characteristics or RF feedback is getting into something (although I would expect immediate changes with RF feedback.)
2. If you are using your antenna for multiple bands, the impedance looking into the 300 ohm transmission line will vary widely, and I think you'll find that a 1:1 choke balun will work better than a 4:1.

73,
Bob AD3K

Subject: [DrakeRadio] Twinlead to Drake MN-4

I'm interested in hearing advice about what would be the optimum method of connecting my 300 ohm twinlead-fed 40 meter dipole to my Drake MN-4 transmatch, as the MN-4 doesn't have provisions for a balanced line feed.

Currently I have the twinlead attached to a homebrew airwound 4:1 balun, and then a short run of 213 coax into the shack to the MN-4. Loads up OK on most bands, but gets a little sketchy on 20 meters: the MN-4 drifts off-match the longer I transmit, requiring retuning.

Thanks to everybody, yes, I should check the voltage going to the marker, first. Maybe the problem is not caused by the ICs.
I also got a reply from the shop, the ICs cost US$10 + 7.5 shipping. I bought a set for spare.
Thanks for your help and suggestion.

Paul -

They show up on EBay all the time. Unfortunately, they sell for more
than you probably paid for the 2-B!!

i believe I'd just get one of the SS versions, stick it in a box with
room for a 6.3VAC to DC supply and plug it in.

From: phbjr@aol.com
Topic: 4193 Message: 4196

I did see a couple on ebay recently, around $135 seems to be the going price.

Actually, I was thinking of "re-creating" a vacuum-tube 2AC by using the schematic in the manual and building it on double-sided plain copper PC board (I have a large sheet of the thin stuff) formed into a "copper box".

What I need is the 4-pin connector. Anyone know of a source? It doesn't have to be a chassis-mount, just the plain-jane 4-pin plug and I can come up with a mounting method.

Paul,

The problem with using tubes with printed circuits is heat. The heating and cooling gradually converts the connections to cold solder joints and then the circuit stops working. Point-to-point wiring is your friend. I had a GE tube type AM-FM radio made with a printed circuit, and when the crashing noises became too annoying I would have to open it up and resolder all the connections to the tube sockets.

The intent would be to use the PCB simply to create a copper box.
Everything would be hand-wired as if it was mounted in a copper chassis.

4200. SPR-4 modification for using a frequency counter

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-20 21:53:32 UTC
From: Hans-Joachim Empel
Topic: 4200 Message: 4200

Good afternoon from Germany .

i am working on one of my SPR-4s.

this one i will modify to read out the receiving frequency.

i know i need a TA-4 board to do this , but i think its an easier way to build a board like the TA-4 board only to mix the VFO - frequency with an easy home bruwed oscillator and read out the RX - Frequency.

Has anybody an easy to build board drawing and can he tell me the connection points on T6 and the Pre Mixer ???

Thanks for any information

Kind regards from Germany

Joachim

Joachim,
I feel I need to let you know that your posts are making it through, even though I cannot help you with your request. I have seen your requests on the Drake lists several times. The SPR-4 is one Drake rig I have not even seen, much less owned, so I have no knowledge of it, hi. I hope you get the answers you need.

From: jeu3pneu
Topic: 4203 Message: 4203

Hi, I wonder how should be the D.C. voltage offset on the T-4XC balanced modulator for full power C.W. mode? I have only about 0.5 V.D.C. so I think it's not enough. There is no indication about this information in the Manual of the radio. Thanks!
Martin VE2EDK

4204. Offer 22 XTALs for Drake SPR -4

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-20 22:03:06 UTC
From: Hans-Joachim Empel
Topic: 4204 Message: 4204

Hello to the Group ,

i modified one of my SPR-4s and i have to offer following XTALs for the SPR-4 (22 XTALs some of them brandnew)

If somebody is interested in the XTALs , please send me a offer , i dont want to sell them via EPAY i prefere a fair price.

Payment via PAYPAL is not a problem.

Shippingcosts are not that high.

11.59 MHz = 0.5 - 1.0 MHz Empfangsbereich auf dem SPR - 4 -1- (Empfangsbereich means RX frequency range)

12.09 MHz = 1.0 - 1.5 MHz Empfangsbereich auf dem SPR - 4 -2-

14.59 MHz = 3.5 - 4.0 MHz Empfangsbereich auf dem SPR - 4 -3-

17,09 MHz = 6.0 - 6.5 MHz Empfangsbereich auf dem SPR - 4 -4-

18.09 MHz = 7.0 - 7.5 MHz Empfangsbereich auf dem SPR - 4 -5-

20,59 MHz = 9.5 - 10.0 MHz Empfangsbereich auf dem SPR - 4 -6-

22.59 MHz = 11,5 - 12.0 MHz Empfangsbereich auf dem SPR - 4 -7-

25.09 MHz = 14.0 - 14.5 MHz Empfangsbereich auf dem SPR - 4 -8-

25.59 MHz = 14.5 - 15.0 MHz Empfangsbereich auf dem SPR - 4 -9-

26.09 MHz = 15.0 - 15.5 MHz Empfangsbereich auf dem SPR - 4 -10-

28.09 MHz = 17.0 - 17.5 MHz Empfangsbereich auf dem SPR - 4 -11-

28.59 MHz = 17.5 - 18.0 MHz Empfangsbereich auf dem SPR - 4 -12-

Subject: [DrakeRadio] Offer 22 XTALs for Drake SPR -4

Hello to the Group ,

i modified one of my SPR-4s and i have to offer following XTALs for the SPR-4 (22 XTALs some of them brandnew)

If somebody is interested in the XTALs , please send me a offer , i dont want to sell them via EPAY i prefere a fair price.

Payment via PAYPAL is not a problem.

Shippingcosts are not that high.

11.59 MHz = 0.5 - 1.0 MHz Empfangsbereich auf dem SPR - 4 -1- (Empfangsbereich means RX frequency range)

12.09 MHz = 1.0 - 1.5 MHz Empfangsbereich auf dem SPR - 4 -2-

14.59 MHz = 3.5 - 4.0 MHz Empfangsbereich auf dem SPR - 4 -3-

17,09 MHz = 6.0 - 6.5 MHz Empfangsbereich auf dem SPR - 4 -4-

18.09 MHz = 7.0 - 7.5 MHz Empfangsbereich auf dem SPR - 4 -5-

20,59 MHz = 9.5 - 10.0 MHz Empfangsbereich auf dem SPR - 4 -6-

22.59 MHz = 11,5 - 12.0 MHz Empfangsbereich auf dem SPR - 4 -7-

25.09 MHz = 14.0 - 14.5 MHz Empfangsbereich auf dem SPR - 4 -8-

25.59 MHz = 14.5 - 15.0 MHz Empfangsbereich auf dem SPR - 4 -9-

26.09 MHz = 15.0 - 15.5 MHz Empfangsbereich auf dem SPR - 4 -10-

28.09 MHz = 17.0 - 17.5 MHz Empfangsbereich auf dem SPR - 4 -11-

28.59 MHz = 17.5 - 18.0 MHz Empfangsbereich auf dem SPR - 4 -12-

31,09 MHz = 20.0 - 20.5 MHz Empfangsbereich auf dem SPR - 4 -13-

31.59 MHz = 20.5 - 21.0 MHz Empfangsbereich auf dem SPR - 4 -14-

32.09 MHz = 21.0 - 21.5 MHz Empfangsbereich auf dem SPR - 4 -15-

32.59 MHz = 21.5 - 22.0 MHz Empfangsbereich auf dem SPR - 4 -16-

38.09 MHz = 27.0 - 27.5 MHz Empfangsbereich auf dem SPR - 4 -17-

38.59 MHz = 27.5 - 28.0 MHz Empfangsbereich auf dem SPR - 4 -18- BRANDNEW

39.09 MHz = 28.0 - 28.5 MHz Empfangsbereich auf dem SPR - 4 -19- BRANDNEW

39.59 MHz = 28.5 - 29.0 MHz Empfangsbereich auf dem SPR - 4 -20- BRANDNEW

40.09 MHz = 29.0 - 29.5 MHz Empfangsbereich auf dem SPR - 4 -21- BRANDNEW

40.59 MHz = 29.5 - 30.0 MHz Empfangsbereich auf dem SPR - 4 -22- BRANDNEW

This is a current point, there are two Ge diode junctions forward biased
to ground, so if you see more than about 0.6 VDC, one of the diodes is
blown!

It is necessary to advance the GAIN control further clockwise for CW
than for SSB. SSB is typically 10 - 11 o'clock, and CW may be 3 - 4
o'clock for full output.

How much output are you getting on CW, on which bands.

4209. Drake R4C PTO characterization

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-21 02:44:52 UTC
From: arsnf7z
Topic: 4209 Message: 4209

per my previous posting about frequency drift at the R4C PTO, I just wanted to report my findings after bringing the culprit into the lab for a more critical analysis.

other than a slightly low zener voltage, ~9.7v, I found the PTO stable and within spec when supplying the +11 volts from the lab power supply. the R4C was off other than external power to the PTO. the problems surfaced only when the R4C was powered on, and heat from the power supply dropping resistors and the audio ouput transistor was introduced. a poor design, to have these heat generators in the near vicinity of the PTO.

the only real solution is to isolate/eliminate the offending components. I'll experiment with shielding to better profile the improvements. this has been addressed before, with a new power supply design and an IC audio stage. not a bad idea, since these are weak areas in the R4C design. better yet, pick-off the audio after the product detector (pre-amp) and route to an external tube stage amplifier, and perhaps, through one of those huge Hammarlund/Hallicrafters speaker cabinets <grin>.

someone mentioned that in finding a replacement speaker for the MS-4, the modern-day 4 ohm speakers were too inefficient for the output stage, and I found this to be true. I'm now looking for the ultimate 'cheap' replacement speaker. the increased low-frequency response while nice for music, isn't optimum for communications signals. CW tends to sound muddy and SSB lacks that mid-range punch that helps on weak signals.

NF7Z, daniel

Hi All,
I just built up two crystal calibrators from Mike Bryce at the HEATHKIT SHOP for use in a 2-c and 2-b. If you the "tube version" this kit includes a relay which switches the dc power on to the calibrator.The relay is powered from the pin supplying plate voltage to the original 2ac. When the calibrator is switched on from the front panel, the relay is activated switching the dc to the calibrator. The calibrator is supplied with ac from the same four pin socket(from orignal fil. pin.) Very clever set up, and you get 25khz and 100 khz steady or pulsed marker. Unless you are a puriest, this is the way to go. I broke and old tube, broke the pins from the base, soldered the wires to pins, then covered with heat shrink tubing. It makes a very nice, and neat installation. .

Joachim,

The spr-4 manual near the back, shows the connection points for the spr4. It looks a t bit confusing at first, but when you look you will see there are pins on the premixer board for direct connection. I built up 2 ta4 replicas, which work fine.....but that leads me to this....

If you are using a DDS VFO why would you want a frq. read out.
I know nothing of your kit, but I bet you have a programmmable offset.
just set this offset to mixer plus vfo (dont have book in front of me) somethin like 10. 5 mhz. then turn the dial to zero and tune all the time with synthisiser. Then you would be reading the freq. received by the radio on the DDS dial all the time.

I am going to purcahse one of dds units from Germany to build up and play with ....I have a n3zi one now, but it only goes to 30 MHZ...or 22 mhz or so on the drake radios. Yours will go through up to 30 mhz on the radio, I can envision my drake 4 line with dds vfo used like an fs4, only tunable!

Ed

Martin -

Before you open the BAL MOD, have him check the values of R104 and R106. It's quite possible that R104 has gone up in value, limiting the current.

It's also possible that there is a problem inside the BAL MOD can, but less likely.

How much output power can you get on the low bands with what setting of the GAIN control????

From: Chuck Pool
Topic: 4219 Message: 4219

Hi to all:
Can the N3ZI DDS2 digital readout system work witht he R-4C and T-4XC?
I would like individual readout for each of the above radios when going split frequency and have both radios sinked together when one PTO is in charge.

Is this possibel and has anyone done this:
73,
Chuck - AA5WG

4223. 200 ohm Carrier Balance Pot

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-08-23 04:25:51 UTC
From: w5rkl
Topic: 4223 Message: 4223

Anyone know of a source or have a spare good 200 ohm Carrier Balance pot (chassis mount)? It's not the multi turn pot like the one in the T4XC. This is a single turn pot. I have some small PC mount 200 ohm muti turn pots but I can't use them in the T4XB. I found it to be bad when I was aligning the T4XB.

I found a couple of new 200 ohm pots at Surplus Sales of Nebraska that appear will work as replacement for the failed Carrier Balance pot in my T4XB transmitter. I ordered them today. Maybe they will arrive by Friday or Monday. Will just have to wait and see. Until then I'll just post pone the alignment segment that requires adjusting the Carrier Balance pot.

Garey, I noticed Drake put a 150 ohm 1/2 watt resistor in parallel with the Carrier Balance pot. This changes the resistance from 200 ohms to 85.71 ohms. Most Carrier Balance pots I have run across on other brand transmitters and transceiver, Heathkit to be specific, only have a 200 ohm pot without the parallel resistor across the pot.

Mike -

Yeah, and you'll note that THEY are all multi-turn pots, too! IF the Bal Mod is balanced 'mechanically', you don't need all that range. Seems you ran into that earlier? Or was that someone else who found that the physical location of the wiring IS critical.

I suspect they chose that resistor to allow for manufacturing variations, small enough to allow enough resolution, and only large enough to provide a sufficient range.

Heath had less control over the 'mechanics', so needed a wider range, and chose a multi-turn pot to get enough resolution.

Garey,

Most of the multi-turn pots I have come across have stops at each end. It typically took 10 turns or so to reach the end. The pot in the T4XB I have appears to not be a multi-turn pot or the pots broken internally. I can rotate it till the cows come home, well over 30 turns either direction, and it never comes to a stop plus it makes no difference in the Carrier Balance adjustment regardless of the rotation position. The Carrier Balance pot in my T4XC is a muti-turn pot and it works.

I don't recall any Heathkit Carrier Balance pots (Heath called it Carrier Null Control) being multi-turn. The SB-400, SB-401, HW-100, HW-101, and the SB-100 series transmitters and transceivers used a single turn 200 ohm pot in the Carrier Balance circuit. If that pot failed then I would replace it with a small PC mount sealed multi-turn pot. I thought about using the small PC mount multi-turn 200 ohm pot (I have 2 spares) but mounting is a problem, I could not come up with a firm mounting and adjustable point at the same place as the original pot was.

Anyway, we'll see what happens when the new pots arrive. They are not multi-turn pots so the adjustment will not be as precise as a multi-turn pot would be.

I am the one who discovered the wiring position had a
strong effect on the modulator balance. My T4-XB was
evidently re-wired by someone, it looked OK until I saw the
photos in your CD, that showed that the two wires going to
secondary of the modulator transformer were reversed. The
symptom was that I could not get a carrier null and the
balance capacitor was out of range. After a couple of false
starts I discovered the wiring error and when it was
corrected was able to get a perfect null with both pot and
cap about mid position.
BTW, the pot in mine is original is is a 400 Ohm pot
rather than the 200 Ohm shown in the schematic.
I chased my tail for a long time on this problem and

damaged the original balance cap which had to be replaced
(overheated it with a soldering iron). This is one reason I
so strongly recommend Garey's CD's. They contain information
NOT included in any of the factory handbooks or anywhere
else including the very valuable photgraphs of the interior
and complete parts lists with location data.
FWIW, the specs for carrier suppression are very good
and the unit will actually do what the specs say. When
adjusted correctly the carrier is so far down it can not be
detected using a good receiver on the output plus the
circuit seems to be pretty stable.

The reduction mechanism on the pot is a ball-bearing
slow motion drive. The stops are those built-into the pot.
If it doesn't stop its either because the internal stops are
broken, or more likely from your description, the pot is
siezed up and isn't actually turning. There is enough slip
in the slow motion mechanism so that it will turn even if
the pot is stuck. Of course, its also possible that the link

from the slow motion drive to the pot is broken. Since you
are gettin a new one it doesn't make sense to try fixing the
old one but it would be interesting to disect it to see what
actually happened to it.

Mike -

That's what I get for trusting my memory..... :-) You'd think I'd learn..... If I listened to Richard, I'd look at my CD and SEE that it is a ball drive.

I don't think the Drake pots have a physical stop. It's a ball drive, and only applies so much torque to the wiper. Perhaps someone 'oiled' the ball drive? You might give it a shot of alcohol to see if that's the case.

Anyway, the parallel resistor just makes the NULL easier to get into with LOTS of resolution.

> Most of the multi-turn pots I have come across have stops at each end. It typically took 10 turns or so to reach the end. The pot in the T4XB I have appears to not be a multi-turn pot or the pots broken internally. I can rotate it till the cows come home, well over 30 turns either direction, and it never comes to a stop plus it makes no difference in the Carrier Balance adjustment regardless of the rotation position. The Carrier Balance pot in my T4XC is a muti-turn pot and it works.
>
> I don't recall any Heathkit Carrier Balance pots (Heath called it Carrier Null Control) being multi-turn. The SB-400, SB-401, HW-100, HW-101, and the SB-100 series transmitters and transceivers used a single turn 200 ohm pot in the Carrier Balance circuit. If that pot failed then I would replace it with a small PC mount sealed multi-turn pot. I thought about using the small PC mount multi-turn 200 ohm pot (I have 2 spares) but mounting is a problem, I could not come up with a firm mounting and adjustable point at the same place as the original pot was.

From: Terrell Hamilton
Topic: 4232 Message: 4232

Good evening to the group -

Does anyone have a Drake AN-5
antenna for a SPR4 they'd like
to sell? If so, my email is
hamilter@...

Topic: 4223 Message: 4233

Rotating the pot does nothing. The new pots, unfortunately, are not multi-turn pots, just single turn 200 ohm pots.

A previous owner was working in that area, putting a toggle switch to turn the AGC ON and OFF that may have damaged the pot. I can say, rotating the pot does not change the Carrier Control setting no matter how many turns the shaft is rotated. I couldn't find a multi-turn pot of the same kind and, as the schematic shows, 200 ohms, so I had to use single turn pots which will not be as precise as a multi-turn pot would be.

Right now the carrier is nulled quite well but having a faulty pot in the transmitter prevents checking the alignment.

The transmitter had no RF output, not a bit, not even a milliwatt. It's fixed now, found a bad 40 meter het crystal and very dirty band switch wafers and relay contacts. The final tubes were weak but once I found the problem and fixed it, the weak finals did produce about 70 watts output. They have been replaced and the final neutralized. I found the neutralizing cap was set to just a few degrees from full mesh. I set it at half mesh to start and only had to rotate it a few degrees to get the final neutralized.

I was checking the alignment and the step called to rotate the Carrier Balance control fully CCW. After rotating the pot 30 turns or more, it made no difference and the IP current remained steady at 70ma, never increased as it should have. I found a number of adjustments that were off, most likely caused by the previous owner trying to find out what was wrong with the transmitter. The 5645Khz CAR oscillator was also off frequency. Looks like the previous owner had his "Golden Screw Driver" in the transmitter.

Garey,

No problem. I'll give it a shot of alcohol and see if that fixes it. I got tired of rotating the shaft so I stopped with the alignment.

I'll have to send you the money and get your CD for the T4XB.

Garey, thanks for your suggestion about these resistors but I've
double-checked all the resistors in this part of circuit and they are all
unfortunately... good...

Martin -

Before you open the BAL MOD, have him check the values of R104 and
R106. It's quite possible that R104 has gone up in value, limiting the
current.

It's also possible that there is a problem inside the BAL MOD can, but
less likely.

How much output power can you get on the low bands with what setting of
the GAIN control????

John -

OK. I think you have some test equipment available. If so the attached
sheet may help you narrow down the problem.

Maybe not so much memory. The original pot in my rig (which is still in there) has a cap soldered to the back to protect the ball race. The replacement someone very kindly sent me does not so that the reducer can be seen. It consists of two races, three balls, and a plastic cage. The balls are driven by a reduced diameter section of the shaft, maybe 1/16" or a bit larger. The cage either carries or drives whatever carries the wiper. The only stop is the internal stop of the pot. If the wiper has been turned too far it will have gone off one end. That should be obvious from a resistance measurement of the wiper to each end. Otherwise its possible that the cage has cracked, that should be visible. Its hard to imagine that lubricant would be so effective that the balls would just turn in place but that should be visible its happening. Its also possible that the wiper has become stuck to the resistance element in some

way. That would stop the rotation. Since the shaft turns freely its also possible the wiper has come loose from the cage. If this pot does not have the soldered on back on it you should be able to see whats going on.

I followed this link from David's post

http://www.wb4hfn.com/Services/WB4HFN/RepairHomePage.htm

Though this is Ron Baker, not John Kriner.

Interestingly, in my very first qso on my TR7, WB9JOX, Ted, recommended this guy highly -- he seemed to know a thing or two about Drakes.

Good to know there are a few good Drake Techs around for us!

Hey David!

I tried http://rldrakeservice.com/ which was supposed to be the link for John and a couple of others. All are dead ends. The link I show here is pending deletion. Guess he's not in the biz any more.

I'll be contacting Jeff.

Thanks to all for the kind assist.

Hi Richard,

The pot in the T4XB has a cap on the bottom that looks to be soldered in place. Therefore, I can't visually look at the ball and shaft mechanism to determine what has happened. When I pull the pot I'll remove the cover to see what has happened. The same pot in my T4XC does not have a cover over the bottom so I can see the 3 balls and the bottom of the shaft movement when rotating the pot's shaft.

I measured the resistance between the wiper and each end while rotating the pot's shaft and the resistance does not change, regardless of the shaft's position.

I don't believe the wiper has slid off the resistance material because if it had then the carrier oscillator signal would not be present at the grid of V2 which would result in no RF output. I can see the carrier oscillator signal at V2's grid and the transmitter does produce RF output.

Whether the wiper is frozen to the resistance material or something else is causing the wiper to not move when the shaft is rotate, I will hopefully find out when I remove the pot and take the bottom cover off.

I don't know what the previous owner to troubleshoot the initial no RF output problem but it does appear he/she did adjust the RF and INJ caps on the left side along with the carrier oscillator in what appears to be steps to determine/fix the initial no RF output problem. The transmitter works now but I want to check the alignment since I found a few of the other cap settings were out of alignment.

Take the pot out and clean it. Pots don't usually fail. But they do get dirty.

If the pot shaft is stuck then the ball drive will just turn continiously with no change in resistance.

You should be able to clean the pot and the ball drive or find someone who can.

Its a standard open type pot. I would start by
squirting some Deoxit into the slot around the terminal
board. and working the shaft back and forth a little. Caig
also makes a pot lubricant. If the wiper has become frozen
to the element there should be some resistance when turning
since the balls can't move and will have to turn against the
outer race. A working pot turns very smoothly. Because the
pot handles only low level RF it might only be dirty. My
concern is that someone may have put enough DC on it to weld
the wiper to the resistance track. If not the contact
cleaner should free it up although it may take several
doses. '

Hi Richard,

I already cleaned the pot with contact cleaner plus blew canned air into the pot's opening after rotating the pot a number of turns in both directions. This was done a couple of times but unfortunately that didn't fix the pot's problem.

I agree, pots do not normally fail and they do get dirty. My plan is to remove the pot, remove the cover, and inspect the pot to see if it's salvageable.

Thanks everyone for your help and information.

Mike,
One thing that has not been mentioned about the checking alignment you have mentioned. Be sure you look on pg 38 of the T-4XB manual and check the slug settings BEFORE you start the alignment. This page tells you how to set the slug rack up to measure each band, and over the years, I have found that someone totally lost and trying to align a broken transmitter WILL tweak the daylights out of these, for some reason. Also, in the CB heyday in the rush to "put the Drakes on 11m", they ALWAYS messed the 28 meg slugs. This will save you a lot of time if checked first. Do mind the cautions about the +250v on S-4a during alignment too!!! Good luck on the carrier balance problem.

I think maybe its just broken. You would have to disect
it to find out what happened. When I thought I had a bad pot
someone was kind enough to send me a replacement, I still
have it. The back is open but you could remove the cap from
yours and install it. I don't even remember if I payed
anything beyond postage for it. If you want it I will send
it to you. I need an address.

I must admit, I am a bit prejudiced. I have had work done by Jeff Covelli, twice, and would not consider anyone else. I shipped all 3 parts to him, each time, and each time it cost me about $82-$84, total, and he included return shipping in my cost. His price was more than fair, and his work was top notch. You can check my rating on eHam, to see more of what I think of his work. But, for me, it was well worth the additional cost, to know they were worked on by the best Drake tech around.

Thanks Don. I have already checked the slugs to ensure they are at the correct height as shown in the manual on page 38 step 4.

I agree, there are people out there that will make adjustments that will create more problems then the equipment initially had, all because they don't know what they are doing. Fortunately the T4XB slugs were not messed with. The RF and INJ caps along with the carrier oscillator and Neutralizing cap were.

The transmitter produces RF output, something it didn't do when I first got it. I did find a bad 40 meter het crystal plus the het oscillator switch wafers along with the other band switch wafers were very dirty. I cleaned them all plus the crystal sockets and the pins on the crystals themselves and with a new 40 meter crystal from International Crystals in OK City, the transmitter works.

Again, thank you for your comments/suggestions, I greatly appreciate each and every one of them.

Date: 2010-08-26 15:43:07 UTC
From: Dave Tipton
Topic: 4254 Message: 4254

I have a complete working (And darn near pristine) TR4 set that I need to offload. (I'm keeping my T4X/R4 combo) I've completely run out of space and want someone who might actually use the thing to have it.

It has been cleaned up, and the one non-standard thing is that the lights have been replaced with blue LED's. The copper is even clean. It's a very nice radio.

I've only used it on 40 and 20, but output power was around 150 Watts without trying to push it. The only thing you'll need is a microphone.

I have videos and photos of the rig on request.

Asking price is $350 + Shipping which would be in 2 boxes, with the AC4 removed from the MS4.

Thanks,
Dave, W5DMT

Topic: 4265 Message: 4265

Hi Everyone,
I am Gary, WB6OGD from Northern California.
Been a ham since 1965 and a Drake lover since, well,
1965!! I have an old R4A/T4X that I will be buried with.. Hi Hi..
I was wondering if someone can tell me what's inside the
"don't ever open it up" Drake PTO. I am wondering because
my R4A has a +/- 2.5KHz cal error difference end to end.. It does
seem to meet the spec (+/-1Khz when calibrated at the nearest
100KHz point, if I recall correctly), but is there anyway
to "tweak" it closer? My T4X (older than the R4A) is only
about +/-1.5Khz.
73,
Gary Winblad

Little parts and magic smoke. :) Seriously, I might have some usable pics of a TR-7 PTO if no one else comes up with anything. Schematics are available elsewhere. Nothing unusual WRT VFO circuits.

> I am wondering because
>my R4A has a +/- 2.5KHz cal error difference end to end..

That's not too bad. Are we getting that picky in this digital age? ;)

Gary -

Welcome to the group.

There's not a whole lot inside the can, BUT 'everything' in there is position sensitive! There is stuff, 'selected' TC caps, etc., hanging in mid air in some of them.

The PTO is specified as accurate to within ? 1 kHz when calibrated at the nearest 100 kHz point, and the total error end-to-end as 3 kHz. There are no linearity adjustments on the PTO.

Best advice is to not open it up except for total failure of a transistor or Zener, and ONLY then, and with great care to not disturb anything!. PTO alignment was considered 'magic' at the factory, there were only a few 'ladies' who set them up with lots of hand-waving while they talked with each other about their grandchildren.

I don't know of anyone who has _successfully_ 'improved' the linearity of a PTO, but I know of several who have managed to make it MUCH worse! :-)

4271. TR-4C Refurbishing & Cleaning.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-09-01 12:48:32 UTC
From: fdonnelly98
Topic: 4271 Message: 4271

Just joined your group. Lots of good info here.
I bought a Drake TR-4C Xcvr from an SK estate. I have brought it back to life and now I want to clean it up. I have removed all tubes and PA shields & front panel. Yes, I made sure I saved the four spacers for the front panel. The top of the chassis is pretty dirty. Looks like a some pitting& corrosion on top surfaces only. Any recommendations on Proper cleaning methods. I don't want to do a complete restoration, just refurbish it.
I have used the 409 & water, & oven method on some R-390A modules with good results, but I am a little hesitant to go that route with my TR-4C. Anybody tried this, or any other suggestions.

Also Where can I find the little red plastic SSB indicator lenses.
I have one missing.
Many thanks in advance
Frank KI0RQ

While we're on this subject, any advice on a dead pto in my T4XC? Trust me, I had reason for doing it, but the whole chassis literally got "the car wash" treatment. For whatever reason, I did not remove the PTO beforehand... Unsure if it was dead before or not, but it surely is now. With external excitation, the xmtr functions perfectly- so not an IF issue. Are there any particular key components that like to "go" in these things? I don't want to poke around too much and risk making it a mini boatanchor...

Most likely the bifilar windings and the core combination are resonating and or the core it saturating. Did you follow the design instructions from a reputable pulication?
I myself got fed up with cheap baluns and paid the $$ for a DX Engineering 4:1 balun. It is rated to 10kW and covers 160 - 10 meters. mainly to avoid the core saturating and then having go non-linear in behavior as it goes into air core inductance mode. The balun is huge when compared to lesser wan'na be balun's.

Chris -

First, are you certain it's the PTO that's dead? A failure of the Band Oscillator or the Preselector will also present as you describe.

The PTO output should be ~2 V p-p and cover from 4.955 to 5.455 MHz at 500 and 000 on the dial respectively.

From: w1kilofoxtrot
Topic: 4277 Message: 4277

I've played around with a number of things, but I'm pretty well convinced the USB filter in the project TR-4C is shot. Seems to have a frequency response of 1800-2800 Hz. Makes 40M LSB and 20M USB communications out of the question.

Anyone have a parts TR-4C or alternate suggestions?

73,
Steve
W1KF

Steve,
INRAD lists new USB and LSB filters on their site. They aren't cheap, but their filters are good!! www.inrad.net will get you to the site, then you can find the TR4 filters from there.

Don,

An interesting thought, and I may wind up going there, except I'd be spending as much on the filters as I spent on the rig.
And MS-4.
And AC-4.
Combined...

I think I'll keep looking around for a while. I still have the entire signal path to re-align, and I can do that by injecting signal as required.

Thanks for the lead!

Have you tried to measure the response of the filter
directly? It may be that there is something else causing the
problem.

Richard,

I have tried measuring the filter response directly, and had less than optimal results. I will give it another shot, but it does seem either that the center frequency of the filter has shifted up 1-1.5 KHz, or the lower edge of the filter has had a similar shift. I'm not aware of what external influence could do that to an 8 pole crystal filter, and I'm pretty sure it's not the local circuit values, since they are shared between the two filters, and the other one is operating as expected.

Thus my (admittedly potentially flawed) theory that the filter is shot. I'm not certain I feel comfortable opening up the filter can to examine the individual components, or what I might to to replace damaged or out of tolerance units.

I am, however, as always, open to suggestion!

73,
Steve
W1KF

Frank,
Mine was a real ugly duckling when I started. I removed the tubes and sprayed the chassis with 50/50 simple green, used a paint brush on some of the tough spots, rinsed it with a hose, then let it set out in the hot sun for 3 days. Following that, I used Deoxit on all switches and tube sockets. As for the SSB indicators, I replaced both with small red LEDs (some would reject that idea) which have a lens almost the same appearance so nobody notices.

Good luck and 73, Dick KF4NS

Just joined your group. Lots of good info here.
I bought a Drake TR-4C Xcvr from an SK estate. I have brought it back to life and now I want to clean it up. I have removed all tubes and PA shields & front panel. Yes, I made sure I saved the four spacers for the front panel. The top of the chassis is pretty dirty. Looks like a some pitting& corrosion on top surfaces only. Any recommendations on Proper cleaning methods. I don't want to do a complete restoration, just refurbish it.
I have used the 409 & water, & oven method on some R-390A modules with good results, but I am a little hesitant to go that route with my TR-4C. Anybody tried this, or any other suggestions.

Also Where can I find the little red plastic SSB indicator lenses.
I have one missing.
Many thanks in advance
Frank KI0RQ

I will repeat here a method of cleaning we used at
Hewlett-Packard a million years ago. The equipment was first
opened up as much as possible. Meters and other water
sensitive parts were removed. The equipment was washed down
with a garden hose and warm water. Then it was spray cleaned
using a paint spray gun loaded with a diluted solution of
dishwashing detergent. After washing it was rinsed
thoroughly with the hose. Then as much water as possible was
blown out using clean compressed air. Then the chassis was
baked in an electric oven at about 130F for a minimum of 48
hours, longer if we had the time. The surfaces can be
scrubbed with brushes or sponges while washing. This process
would usually would leave the chassis looking new.
But, you need an air compressor capable of delivering
oil-free air, and a paint spray gun. You could probably do
an adequate job of drying using IR lamps instead of the
electric oven.

I don't have any specific suggestions, its just that the cost and difficulty of replacing the filters seems to me to justify the effort of making sure they are the problem. Lattice filters are sensitive to the terminal impedances so that may be a place to look. However, if both filters are fed from the same source and terminated the same way that's probably not the source of trouble. Lattice filters are quite sensitive to variations in their components, the more poles the more sensitive, so something could well have changed inside including failure of one of the crystals. I think its less likely that the center frequency changed than that one of the skirts moved. Good luck on this.

Hi Dick; I bit the bullet and used the water method.
I removed all tubes, and dial cover, meter, final cage and then
I went to the drug store and bought some finger cotts. I slipped one over each transformer can and then covered the VFO real good, and bought those small green round furniture pads and stuck one to each tube socket to keep direct water out.
I then sprayed the whole thing with 409 cleaner and used the paint brush. After it soaked good I rinsed it with the hose until no suds came out, then I rinsed it with distilled water. My TR-4C had some bad pitting on the chassis. Could not get it off.
After leaving it in the sun and turning it a few times I used my hot hair dryer real good. then I cleaned the tubes (found three completely bad tubes. Heaters open. After putting it all back together I turned it back on. and "wad ya know" NO SMOKE.
I then left it on so it would warm up good just to make sure there was no water left anywhere. Now I will use Deoxit on all contacts, switches, and tube sockets. I have done this before on an R-390A.
So far all working good.
Thanks for your comments
Frank KI0RQ
